IV. *The Carbon Dioxide Absorption Technique* (twenty-four minutes).—Animated drawings have been used extensively to illustrate the absorption of carbon dioxide from anesthetic atmospheres. The drawings are undoubtedly very helpful in simplification but seem not so well done as in some other films of the series. Ease of understanding would be promoted if the representation of respiratory movements was made continuous as they occur naturally rather than with periodic interruption. A useful film until a better one becomes available.

V. *Endotracheal Anaesthesia* (twenty-six minutes).—This deals with technic only. A well thought out representation of the subject with excellent photography and "acting." The simple details are depicted in a manner designed to help the neophyte to a working knowledge. The necessity of brevity has apparently caused the omission of the disadvantages and difficulties while emphasizing the desirable features. No mention is made of the possibility of respiratory obstruction even though the larynx has been intubated. Details of cleansing the upper and lower tracts before extubation are omitted. However, the film has distinct value as an aid in teaching endotracheal technics to students and prospective anesthetists who have had no previous experience.

VI and VII. *Intravenous Anaesthesia* (thirty and twenty-five minutes.—These two films deal with elementary technical details of the intravenous administration of pentothal sodium. Probably necessary for wartime instruction but of little value in this country at this time.

VIII. *Spinal Anaesthesia* (thirty-four minutes).—Technical details only, of the use of one drug (nupercaine). The handling of needles and other equipment in the manner of performing spinal puncture will seem clumsy to some American anesthetists. The use of 1:200 nupercaine is not generally accepted in this country at the present time. The apparent neglect of observation of the blood pressure and pulse as a guide to the control of the condition of the patient is disappointing. The photography is beautiful, as is the aid of animated drawings. It would be undesirable if not dangerous to show this picture to general and undiscriminating audiences.

IX. *Respiratory and Cardiac Arrest* (fifteen minutes).—The purpose inspiring the preparation of this film is good and the representation of the subject to the profession is important. The execution here depicted leaves much to be desired. The importance, in an emergency, of simple prompt inflation of the lungs with oxygen by the anesthetist seems to have been neglected in the effort to illustrate the more spectacular but less frequently needed cardiac massage. Interesting to medical audiences no doubt but of doubtful teaching value.

X. *Operative Shock* (sixteen minutes).—Many anesthetists would question whether well conducted deep anesthesia is necessarily a cause of shock. The assumption is made that flow meters rather than the patient afford dependable evidence of whether the patient is well supplied with oxygen. The emphasis is often placed on "drops per minute" and other extrinsic evidences rather than on the condition of the patient. The photography and graphic representations are again excellent. One might question whether the subject of shock is one which lends itself to consideration by the use of the cinema. Perhaps it was justified as a military measure, but this film scarcely deserves wide showing in peacetime.

XI. *Handling and Care of the Patient* (twenty-six minutes).—Much detail and some humor represent good things and bad things to do in handling patients in the operating room and in their beds after operation. Although different equipment is used than that commonly available in this country, the film ought to prove most valuable in the instruction of nurses, orderlies and other attendants who help with the care of patients. The points stressed certainly ought to be, but are not, second nature to every American physician. Therefore, the showing of this film to any medical or allied audience will prove diverting as well as instructive.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dentists: Unauthorized Extraction of Teeth.—The plaintiff sued for damages for the wrongful removal of five teeth by the defendant dentist. From a judgment in favor of the plaintiff the defendant appealed to the district court of appeal, first district, division 1, California.

The plaintiff alleged that he visited the office of the defendant, a duly licensed dentist, for the purpose of having one designated tooth extracted. He was placed in a dental chair and an anesthetic was administered. While he was under the influence of the anesthetic, the defendant "carelessly and negligently" and without the plaintiff's consent extracted from the plaintiff's jaw five teeth in addition to the one which he had designated. Certain evidence came into the case under the following circumstances: The plaintiff was called as the first witness, but shortly after he started to testify, Dr. Hendricks, a San Francisco dentist, whose qualifications are not questioned, was permitted to take the stand, by consent, out of order. Over defendant's objections Dr. Hendricks was permitted to testify that when a tooth shows signs of decay or has a hole in it there are other remedies besides extraction, namely the insertion or installation of fillings, crowns or inlays; that it is customary practice in San Francisco to take an x-ray before extracting a tooth.

It is the theory of the defendant that the complaint charges the removal of five teeth without the consent of plaintiff and it is urged that such a complaint charges an assault, that negligence is no part of a cause of action for assault and that it was therefore error to admit evidence and to instruct on the subject of negligence.

After the defendant had objected to the questions asked Dr. Hendricks, said the court of appeal, the trial court indicated that it interpreted the complaint as charging negligence. Therefore the defendant knew that negligence was an issue shortly after the opening of the trial. Furthermore the defendant himself introduced evidence on such issue. He testified that x-rays were unnecessary for two reasons: In the first place, plaintiff did not want to pay for them; in the second place, the teeth in question were so badly diseased that it was obvious extractions were in order. He also testified that because of the condition of the teeth it would have been impossible to fill or crown them and that had they remained in plaintiff's mouth they would have impaired his health. Plaintiff testified that the five teeth in question were in good condition and that the defendant at no time suggested that x-rays be taken. At the close of all the evidence the plaintiff moved to amend his complaint to conform to the proof so as to allege specifically that it was the custom in the community to take x-rays before making an extraction. This motion was denied on the ground that the complaint generally alleged negligence and that it was not necessary to set forth the evidentiary facts. The complaint charged not only that the extractions were made without consent but also that they were negligently and carelessly made. If negligence is charged and evidence is introduced on the issue, it is proper to give instructions on the standard and the degree of care required of a medical man. Accordingly the court of appeal held that the evidence had been properly admitted under the plaintiff's complaint and the judgment in favor of the plaintiff was affirmed.—*Estrada v. Orwitz, 170 P. (2d) 43 (Calif., 1946).*

Hospitals, in General: Liability for Injuries to Invitee.—The plaintiff obtained a judgment against the defendant hospital for damages resulting from a fall in the hospital lobby, from which judgment the hospital appealed to the United States Court of Appeals of the District of Columbia.

The plaintiff entered the defendant hospital for the purpose of visiting a patient. It was then the middle of the afternoon and it had been raining almost continuously since 8 o'clock that morning. The floor of the lobby was highly polished and had become wet from people passing over it with wet shoes and dripping umbrellas. The court of appeals said that, from the evidence produced, the jury could have inferred that the floor was visibly and palpably wet at 2:45 p. m., the time the plaintiff slipped and was injured, and the accumulation of water was a continuous process ever since the floor was mopped at 8:30 in the morning. The jury might fairly think, the court continued, that due care required the hospital during this time to discover that this gradual wetting process was going on, or to realize that it must be going on, and to make some effort to obviate it. The hospital, however, made no such effort during the six hours which elapsed between 8:30 a. m., when the floor was gone over with a dry mop, and the time of the accident. Accordingly, said the court, reasonable men might conclude, as the jury did, that the floor was wet by reason of negligence on the hospital's part. Whether this court would or would not have reached the same conclusion, added the court of appeals, is of course immaterial. The evidence also supported the conclusion that the wet floor was one of the causes of the plaintiff's fall. Falls are more likely on wet floors than on dry ones. Furthermore, standing water is more effective than damp shoes in reducing friction or traction between floors and shoes and is more likely to cause falls. Even if the previous dampness of the plaintiff's shoes was one cause of her fall, the hospital was responsible if its negligence was another cause. The evidence justified the inference that the wet floor was at least a contributing cause of the fall. The alternative inference, that the plaintiff's damp shoes were the sole cause of her fall, might reasonably be thought quite improbable. The evidence therefore supported the jury's verdict, concluded the court of appeals, and the judgment in favor of the plaintiff was affirmed. —*Doctors Hospital, Inc., v. Badgley, 156 F. (2d) 569 (1946).*

Charitable Hospitals: Criteria of Tax Exemption.—The plaintiff hospital filed suit against the city of Corpus Christi, seeking cancellation of certain taxes assessed by the city against land owned by the hospital, and on which the hospital was conducted. Exemption from taxation as a public charity was claimed under section 2, article 8 of the Texas constitution and section 7, article 7150, Vernon's Annotated Texas Statutes. Judgment of the trial court was rendered in favor of the hospital, canceling the taxes and enjoining the city from seeking to collect them. Accordingly the city perfected an appeal, which the Supreme Court assigned to the court of civil appeals of El Paso, Texas.

The plaintiff hospital was organized in 1924 as a charitable corporation. It was built with funds donated by the Protestant churches and organizations within the city and adjacent territory. Its corporate purposes are purely charitable; it has never declared a dividend and it is not legally competent so to do. Its officers and directors receive no compensation. Since 1939, when the hospital lands were taken into the city limits, it has been operated in accordance with a contract executed between the hospital and Mr. and Mrs. Ed Sizer Jr. Under the terms of this contract the administrators, Mr. and Mrs. Sizer, had the following obligations: to pay the corporation $300 per month, this to be paid although they might operate the hospital at a loss; to pay all operating expenses from the current revenues of the hospital, and to devote all their time to the administration of the hospital. After the discharge of these obligations the administrators had the right to retain all the revenue of the hospital as their own; likewise they had the uncontrolled discretion to fix the rates for all hospitalization and to collect therefor. They likewise by fair implication had, said the court, the right to exclusive possession of this property.

It is very clear, said the court of civil appeals, that if any charity was extended in the operation of this hospital it was at the expense of the administrators. They were in no way bound to extend charity to anyone. On the payment of $300 per month and the current expenses they had untrammeled control of the hospital. The corporation had no right to employ or discharge a single employee, or to control one in any manner. The corporation had no contractual relationship with those receiving hospitalization. In the opinion of the court, the relationship created by the contract has many of the elements of that of landlord and tenant; the administrators paid the corporation $300 per month for the privilege of operating the hospital for their own benefit. It is true, continued the court of appeals, they were bound to devote their entire time thereto, but after shouldering the burdens imposed by the contract they were entitled to all profits made in the operation. A charitable corporation operating a hospital on its own property may, out of the revenue derived, pay the expenses of operation, including salaries of employees; but for the property to be exempt from taxation the corporation must itself operate the hospital, and the entire property must be devoted to purely public charity. Whether the contract under which the administrators conducted this hospital be called a lease or an operating agreement, the hospital was not operated by the corporation through its agents or employees. Accordingly the judgment in favor of the plaintiff hospital was reversed, and judgment was rendered in favor of the defendant city.—*City of Corpus Christi v. Fred Roberts Memorial Hospital, 195 S. W. (2d) 429 (Texas, 1946).*

Council on Medical Education and Hospitals

PLAN FOR UNIFORM INTERN PLACEMENT

A new agreement for internship placement was formulated at a meeting of the Committee on Internships and Residencies of the Association of American Medical Colleges, at Edgewater Park, Miss., on Oct. 28, 1946. Representatives of the Council on Medical Education and Hospitals of the American Medical Association and of the American Hospital and Catholic Hospital associations participated. Although it was not possible for the American Protestant Hospital Association to send a delegate, the plan as subsequently adopted was approved by the trustees of that association. Following unanimous approval at the executive session of the Association of American Medical Colleges, the Council on Professional Practice of the American Hospital Association and the Council on Medical Education and Hospitals of the American Medical Association took confirmatory action. The plan has been submitted to the Catholic Hospital Association and it is hoped that its confirmation will be announced shortly.

DETAILS OF PLAN

1. That letters of recommendation by faculty members as a hospital requirement should be eliminated, all information about applicants being centralized in the deans' offices and credentials sent out from there. (This action was taken in an effort to relieve overburdened faculty members of the task of writing an increasing number of letters of recommendation to support internship applications. Also it was hoped that the information from the faculty might be assembled in the dean's office and then incorporated in one letter of recommendation. This should simplify the work of the hospitals in reviewing the records and recommendations on each case.)

2. That the hospitals be requested to eliminate statement from intern application blank that the student will agree to accept if appointed.

3. Date for filing applications and release of credentials by the medical schools set at Oct. 15, 1947. (These dates are for internships beginning July 1, 1948.)

4. Appointment date by hospitals not before Nov. 15, 1947. (These dates are for internships beginning July 1, 1948.)

5. No specific waiting period following announcement of appointments. Hospitals will be requested to notify all applicants of acceptance, alternate position or rejection (with the understanding that notification of rejection may be made by the hospital at any time). (Rejection notices may be sent as soon as decision is made, any time before appointment date or as soon as possible after that date.)

6. Notification is to be sent to the hospitals that it is anticipated that dates for filing release of information and appointment will be moved further into the senior year in 1949. (For internships beginning in 1949.)

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS
EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in The Journal, Jan. 18, page 199.

BOARDS OF MEDICAL EXAMINERS

Arkansas:* *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination.* Los Angeles, March 10-13. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

Connecticut:* *Medical. Examination.* Hartford, March 11-12. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

Georgia: Atlanta and Augusta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

Illinois: Chicago, Jan. 28-30. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.

Indiana: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

Iowa:* *Examination.* Iowa City, March 17-19. Corresponding Sec., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

Maine: Portland, March 11-12. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

Massachusetts: Boston, March 11-14. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston 33.

Missouri: *Examination:* Kansas City, Jan. 27-29. Exec. Sec., Department of Education, Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

Montana: Helena, April 1-2. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

Nebraska:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

Nevada: *Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

New Hampshire: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

New Mexico:* Santa Fe, April 7-8. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

New York: Albany, Buffalo, New York and Syracuse, Jan. 27-30. Sec., Dr. Jacob L. Lochner, Education Bldg., Albany.

Pennsylvania: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

Texas: *Examination.* Galveston, Feb. 20-22. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

Vermont: *Examination.* Burlington, Jan. 31-Feb. 1. Sec., Board of Medical Registration, Dr. F. J. Lawliss, Richford.

Washington: *Examination.* Seattle, January. Sec., Mr. Nelson Vaughn, Olympia.

Wyoming: Cheyenne, Feb. 3. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Connecticut: Feb. 8. Address State Board of Healing Arts, 250 Church St., New Haven.

District of Columbia: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

Florida: May 31. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

New Mexico: Santa Fe, Feb. 2. Secretary, State Capitol, Santa Fe.

Oklahoma: Oklahoma City, March 17. Sec., Dr. J. D. Osborn, Jr., Frederick.

Oregon: Portland, March 1. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

Rhode Island: Providence, Feb. 12. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days Three journals may be borrowed at a time Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested) Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

72:371-500 (Oct) 1946

Preclinical Stage of Infantile Hypertrophic Pyloric Stenosis. A. Wallgren —p 371.
*Congenital Deafness and Other Defects Following German Measles in Mother Louise A Hopkins —p 377.
*Reenforcing or "Booster" Injection of Pertussis Vaccine in Previously Immunized Children of Kindergarten Age: Pertussis Field Series V. Pearl Kendrick, Grace Eldering and Mary Thompson —p. 382.
Speech Therapy for Children with Cerebral Palsy. M. A. Perlstein and Marie Shere — p. 389
Convulsions in Childhood: Twenty Year Study of 2,500 Cases M. G Peterman —p 399
Recurrence of Infection Following Therapy with Sulfonamide Compounds and Penicillin P E. Rothman.—p 415

Congenital Deafness Following German Measles in the Mother.—Hopkins suggests that rubella occurring early in pregnancy may be the cause of certain cases of congenital deafness that have formerly been unexplained. Ten such cases are reported in which the mother had German measles during pregnancy. Two cases in which the mother did not have German measles but had another virus disease, influenza, and 6 cases in which the mother did not have any virus diseases during pregnancy but in which the child exhibited some of the same congenital defects are also listed.

"Booster" Injections of Pertussis Vaccine.—Immune response as measured by the opsonocytophagic reaction was studied by Kendrick and her associates in 187 children before and after a stimulating injection of plain pertussis vaccine given at the time of entry into kindergarten Tests before the "booster" dose suggested that a moderately high level of opsonic activity was maintained for as long as four years after primary immunization Tests after the "booster" injection showed reactions on the average 1.6 times those before the injection, and the average increased from the moderate range to that of strong reaction. The results lend experimental support to the policy of giving a "booster" injection of pertussis vaccine to children just before they start school, when the likelihood of exposure to whooping cough is greatly increased

Comparative Study of Water, Salt and Heat Exchanges of Men in Tropical and Desert Environments G W. Molnar, F J Towbin, R E Gosselin and others —p 411.

Lithium Antimony Thiomalate in Filariasis—Brown and Thetford made observations on natives of St Croix, Virgin Islands They found that lithium antimony thiomalate given intramuscularly to patients infected with Wuchereria bancrofti produces a rapid diminution in the number of circulating microfilariae which so far has persisted for two years. The antimony blood plasma levels and erythrocyte levels in patients successfully treated did not differ appreciably from those of a patient unsuccessfully treated No evidence of inflammation or incipient elephantiasis has been detected in the patients over a period of two years

Efficacy of Cox-Type Vaccine in Typhus.—Gilliam says that experience among employees of the Cairo Fever Hospital suggests that three doses of Cox-type vaccine, as manufactured late in 1942, afforded some protection against an attack of naturally occurring louse-borne typhus fever. One or two doses of this vaccine did not offer much protection against attack

Experimental Studies in Cardiovascular Pathology: XIV Experimental Atheromatosis in Macacus Rhesus Monkeys W C Hueper.—p 1287
Metastatic Calcification Associated with Hypervitaminosis D and Haliphagia R. M Mulligan —p 1293.
Pathological Calcification in Gingivae W. F. Barnfield —p 1307.

Fatal Hookworm Disease. — Postmortem examinations carried out on Guam in 1945 on 50 children of 4 years of age and under revealed that in 21 instances the primary cause of death was hookworm disease with its attendant complications. Serious terminal infections, chiefly of the respiratory tract, often obscured the underlying hookworm disease The most important lesion of hookworm disease was acute *jejunitis*, which progressed in some cases to produce widespread ulceration, hemorrhage, necrosis and even gangrene of this part of the intestinal tract. In 6 cases there occurred an extensive purulent peritonitis A prominent feature of the intestinal lesion was the infiltration of eosinophilic leukocytes.

Spread of Neoplastic Cells Through Respiratory Passages.—Furth observed that carcinoma cells instilled into the nostrils of lightly anesthetized mice reached the lungs and produced large tumors Leukemic cells of a lymphoid strain similarly introduced produced fatal leukemia with no gross pulmonary changes Leukemic cells of four other strains produced tumor-like pulmonary infiltrations, with spread to regional lymph nodes terminating in generalized leukemia

Thickness of Skin Grafts.—Padgett maintains that many of the advantageous properties of skin grafts, provided a good "take" can be obtained, become greater, the thicker the skin graft has been cut; on the other hand, the disadvantageous properties, except that of a certainty of a "take," increase as the thickness of the skin graft decreases. There are four different thicknesses of sheet skin grafts: (1) Thiersch graft, which is supposed to contain only the epithelial layer, but which usually contains also some corium; (2) the superficial and intermediate "split skin" graft, which extends to one-third or two-thirds of the skin depth; (3) the so-called "three quarter thickness" skin graft which takes in from 75 to 90 per cent of the skin depth, and (4) the full thickness skin graft which includes all skin layers. Thin skin grafts are generally used in adults to cover granulating areas and to reline cavities. "Three quarter thickness" skin grafts are used not only after release of healed or nearly healed contractures and to cover aseptic denuded areas or cavities but also on the neck and face. In children full thickness skin grafts are used when small areas are to be covered and in web fingers.

Local Use of Ice After Orthopedic Procedures.—Following surgery or manipulation Schaubel used ice caps on 345 of 824 patients; ice was not used on the remaining 479 patients. Immediately postoperatively the cloth-covered ice bags are applied to the plaster or soft bandage over the operative site. The ice caps are refilled every four hours and are used for forty-eight hours postoperatively. The accumulated air in the ice caps should be released at hourly intervals to allow them to hug the cast snugly. Schaubel found that in the patients in whom ice was used locally fewer casts were split; the temperature, pulse rate and respiratory rate were lower; white blood cell counts were nearer normal; postoperative complications were fewer, and the amount of narcotic needed was reduced. Subjectively, the patients who have ice applied locally fare better in all respects than the patients who have no ice application.

Specific Cytotoxic Action of Tuberculin: Studies on Tissues of Tuberculous Rabbits in Which Negative Cutaneous Reactions to Tuberculin Have Developed. Dorothy H. Heilman and W. H. Feldman.—p. 312.

Streptomycin in Clinical Tuberculosis.—Hinshaw and his associates treated 10 patients with generalized hematogenous tuberculosis with or without meningitis with streptomycin. Four patients are still living, but persistent clinical observations indicate the possibility of residual infection. The 4 surviving patients are the only ones who were given streptomycin intrathecally. Nineteen of 24 patients with pulmonary tuberculosis improved sufficiently to suggest that streptomycin was a factor in altering the unfavorable trend noted before treatment with streptomycin. There was also a prompt response in 6 cases of ulcerating tuberculosis of the respiratory tract. Streptomycin seems primarily of palliative value in tuberculosis of the urinary tract. Improvement in excess of what might be expected from pleural lavage was observed in only 1 of 7 cases of tuberculous empyema. The authors conclude that at this time streptomycin cannot be recommended as a substitute for long established therapeutic procedures.

Antimony Compounds in Tuberculosis.—Rose and his associates treated tuberculous guinea pigs intensively with the antimony compounds Anthiomaline (lithium antimony thiomalate), fuadin (stibophen), neostam (stibamine glucoside) and neostibosan (ethyl stibamine). The results indicated that antimony, thus administered, did not exert a deleterious effect on the course of the tuberculous infection. On the contrary, fuadin, neostam and neostibosan apparently have a slight but definite restraining influence on the infection.

Contact Dermatitis from Penicillin.—Friedlaender and his co-workers observed contact dermatitis in 5 persons handling penicillin. Investigations were made in 4 of these cases to determine whether the source of the sensitizing agent was penicillin or the impurities contained in the commercial preparation. In 3 cases a sensitivity to the active principle of penicillin was determined. No relationship between contact dermatitis due to penicillin and clinical allergy to molds was observed. It is pointed out that contact dermatitis may occur in many patients receiving topical penicillin therapy.

Rhinoscleroma.—According to Reyes rhinoscleroma is a tumor formation of waxy or reddish appearance with a decided tendency to ulcerate and spread. It has been ascribed by Frisch to a bacillus of the Friedländer type, but the author's research work is focused on the theory that rhinoscleroma is caused by a filtrable virus. It is a chronic disease which transforms the countenance of the patient to such an extent that he resembles a rhinoceros. The disease develops in three stages, the period of rhinitis, the infiltrating period and the nodular period. Mortality varies with the localization and extension of the lesion. For patients with laryngeal localization with extension to the trachea, asphyxia by obstruction is the constant threat and tracheotomy is required to save the patient's life. There may be recurrences, and the patients may end up with pulmonary tuberculosis or the lesions may become malignant. The author regards roentgen irradiation or intramuscular injection of azosulfamide as the most effective treatments and thinks that with early treatment the disease is curable.

Culture Method in Cutaneous Leishmaniasis.—Dostrovsky and Sagher stress that the varied clinical picture of cutaneous leishmaniasis (Oriental sore) makes an objective diagnostic method highly important. Since in the atypical and late types of the disease the microscopic demonstration of parasites often fails, the authors have given their attention to the diagnostic significance of the culture method, which they describe. The results in 31 cases of leishmaniasis nodosa and leishmaniasis ulcerosa and in 30 cases of leishmaniasis recidiva are presented in evidence of the possibility that parasites can be demonstrated in cultures. In 26 cases the cultures were the only means of establishing the presence of parasites.

Electrocardiogram in Hypertension.—Filley attempted to determine what meaning, if any, can be attached to the term "left ventricular strain." One hundred selected cases of arterial hypertension were analyzed, and the findings were correlated with the limb lead electrocardiogram in each case. Inversions of T waves and ST segment depressions in lead 1 or in leads 1 and 2 were associated primarily with high diastolic arterial pressure, coronary sclerosis, and hypertrophy of the heart as a whole. These ST-T changes were not significantly related to an increase of thickness of the left ventricular wall relative to that of the right ventricle. The poor prognosis usually associated with this electrocardiographic pattern was shown to depend largely on other prognostic signs. The pattern of "left ventricular strain" was not in itself an indication that the myocardium had failed or was about to fail.

- Some Aspects of Aviation Dentistry. K. F. Knudtzon.—p. 494.

Effect of Amphetamine Sulfate on Pilots.—Amphetamine sulfate had widespread use in military aviation for combating fatigue, and presumably its use will be resorted to by pilots. Newman investigated the possibility of this drug having some deleterious effects on pilot performance. He found that amphetamine sulfate by mouth in a dose of 10 mg. improved the performance of 3 fainters on the tilt table test. In 10 nonfainters there was considerable variation in the effect of the drug with a general tendency toward improvement of performance. The author thinks that in the great majority of subjects amphetamine produces increased resistance of the circulation to postural changes, and that from this point of view the use of amphetamine by flying personnel is not contraindicated.

Penicillin Resistance.—According to Dowling and his co-workers penicillin G is the fraction of penicillin which is best known and most used, but penicillin F and B have also been isolated in the crystalline form. Since penicillin X is being manufactured in appreciable quantities, the authors decided to investigate whether it is superior to penicillin G. They tested 101 strains of bacteria from human sources for their sensitivity to the two penicillin fractions X and G. They found that organisms which cause human infections usually do not show great differences in their relative sensitivity to penicillin G and penicillin X. In most instances, when resistance to one of these fractions increases, resistance to the other fraction will also increase.

Methemoglobinemia in Infants Due to Well Water of High Nitrate Content.—Faucett and Miller report 2 newborn infants with proved methemoglobinemia who were successfully treated with injections of methylene blue and a third infant who probably had methemoglobenemia and recovered spontaneously. The methemoglobinemia in all 3 infants was associated with ingestion of milk mixtures diluted with well water containing a large amount of nitrate ions. The authors suggest that special precautions be taken in rural areas to see that any water used in the feeding of infants is safe in respect to its nitrate content.

Diagnosis of Abortive Poliomyelitis.—Bridge studied illnesses of 1,123 close contacts of patients with poliomyelitis. The ages of these contacts varied between 6 weeks and 74 years. When the various symptoms were reviewed in respect to the age of the persons concerned, it was noted that fever was particularly common in children below the age of 10 years, headache among the 10 to 40 year group, and diarrhea in the older subjects. Nausea, vomiting and sore throat affected the various age groups in approximately the same proportion. In the absence of laboratory aids to verify the diagnosis, the following circumstances assist in reaching a conclusion: (*a*) similarity of symptoms to those known to occur in mild illnesses caused by the poliomyelitis virus; (*b*) evidence of an incubation period of from one to three weeks; (*c*) the presence of known cases of poliomyelitis in the neighborhood, and (*d*) occurrence during warm weather.

Diarrhea Epidemic in Newborn Nursery Secondary to Milk-Borne Epidemic.—Ensign and Hunter describe an epidemic of diarrhea secondary to a milk-borne epidemic of diarrhea in the community. The infecting organism was Pseudomonas aeruginosa which gained entrance to the milk supply through a rag which dripped into the pasteurized milk of one dairy. The contaminated milk caused an epidemic of gastroenteritis in Great Bend, Kan., and caused outbreaks among patients and employees of the hospital. The infants were secondarily infected by mothers and nurses who drank the milk in the hospital or by other members of the family after the infants had been dismissed from the hospital. There were 24 newborn infants who contracted the diarrhea. Ps. aeruginosa was isolated from the stools of all 9 who were studied bacteriologically. There were 9 deaths among the 24 newborn infants. The epidemic subsided after proper control measures had been taken.

Chondroma of Eighth Costal Cartilage.—p. 663.

Islet Cell Tumor of Pancreas with Hyperinsulinism.—Marble and McKittrick review observations on 6 cases which illustrate the various problems encountered in the diagnosis and treatment of patients with hyperinsulinism. In 5 of these removal of a single adenoma resulted in the relief of symptoms that had persisted from four to seven years after operation. In 1 case death followed seven weeks after a surgical operation which disclosed an islet cell carcinoma with multiple metastases in the liver. In the 4 cases in which assays were carried out, the insulin content ranged from 3 to over 100 units per gram of tumor tissue. The important features in the diagnosis of islet cell tumor are the characteristic symptoms associated with hypoglycemia (blood sugar concentrations usually below 50 mg. per hundred cubic centimeter) brought on by fasting, increased by physical exertion and relieved by food. The dextrose tolerance test is of aid in diagnosis only if carried out for four to six hours to allow the blood sugar to fall to an abnormally low level. Because of the danger of damage to the central nervous system by repeated attacks of prolonged hypoglycemia and because of the possibility of malignant degeneration of the tumor early exploratory operation is urged in patients in whom the diagnosis of islet cell tumor with hyperinsulinism has been made.

Age and Clinical Effectiveness of Nitroglycerin Tablets.—Sagall and his associates investigated the clinical effectiveness in patients with angina pectoris of eleven preparations of hypodermic tablets of nitroglycerin, in dosages ranging from 0.6 to 0.1 mg., at periods varying from a few months to eleven years after manufacture. There was no essential loss of clinical effectiveness in the old tablets as compared to fresh tablets of the same dosage. Fresh tablets exposed to heat of 98.6 F. (37 C.) for three months showed a complete loss of clinical potency, whereas tablets that had been carried by patients in the customary manner for four months showed no loss of clinical effectiveness.

Appendicostomy in Chronic Ulcerative Colitis.—Yeomans, in briefly reviewing the indications for appendicostomy, says that, in comparison with transverse ileostomy or complete colostomy, appendicostomy is a minor procedure. He describes the technic of appendicostomy and pleads that it be used as the initial measure when surgery proves necessary in chronic ulcerative colitis. He reports a case in which succinylsulfathiazole was introduced directly into the colon through the appendix stoma with excellent results.

Reconditioning—Management of Convalescence. R. W. Lippman.—p. 2421.

Management of Peptic Ulcer Patients.—Ruggiero and his co-workers administered protein hydrolysates to 134 ambulatory patients with peptic ulcer. The patients were given the protein hydrolysate in amounts sufficient to supply 0.6 Gm. of nitrogen per kilogram of body weight, and in addition dextrimaltose number 2 was given so as to supply between 40 and 50 calories per kilogram of body weight. In the 134 cases treated there were 16 failures. One hundred and eighteen patients no longer had any clinical symptoms or signs referable to peptic ulcer. They gained weight if they were underweight at the start of treatment. Their strength and desire to work increased. Insomnia and general nervousness disappeared.

Surgical Treatment of Phantom Limb.—Browder and Gallagher present a preliminary report of their study of 100 adult patients with absence of one or more extremities. Interruption of proprioceptive sensibility of the involved part seems to be the only probable method for the relief of enduring painful phantom limb and was accomplished by section of a dorsal column of the spinal cord in 2 patients with the typical syndrome of viselike fixed abnormal posture of a ghost foot and in 1 with phantom forearm and hand.

Rickettsialpox.—Huebner and his associates state that during July 1946 a peculiar febrile disease characterized by an initial lesion and an eruption of a vesiculopapular type was reported in a housing development in New York city. Because of a clinical resemblance to chickenpox and because the organism isolated from 1 patient has the morphologic and cultural characteristics of rickettsias, the name "rickettsialpox" is proposed. This organism produces illness in mice and guinea pigs and grows well in the yolk sacs of fertile eggs. Ether-extracted yolk sac antigens have been prepared which fix complement with convalescent serums drawn from typical cases. This reaction is apparently specific insofar as it has been tested, except for cross reactions with Rocky Mountain spotted fever.

Angiographic Diagnosis of Intracranial Lesions.—List and Hodges studied the displacement of intracranial blood vessels in 136 patients with space-occupying intracranial lesions by means of carotid or vertebral angiography. This method, which has proved to be reliable and safe, is suggested in certain expanding lesions of the base of the brain and the skull, and of the cerebral space-occupying lesions of the cerebral hemispheres which have been grossly localized, or at least lateralized, by other diagnostic methods. It is of special value for the differentiation of neoplasms and vascular processes.

Retrograde Abdominal Aortography.—Fariñas reports the principal inflammatory and degenerative processes encountered in the retrograde arteriographic study of the abdominal aorta and iliac arteries in 6 patients between the ages of 30 and 74 years. The method consists in exposure of the femoral artery by blunt dissection under local anesthesia at the level of Scarpa's triangle and its puncture with a trocar, through which a solution of diodrast is injected in two and a half to three seconds. The first film is taken when 40 cc. of the opaque substance has been injected and a second one immediately afterward. By aortography valvular kinks have been demonstrated for the first time whose surgical removal benefits greatly the circulation of both extremities.

Eosinophilic Granuloma of Bone.—Dundon and his associates point out that the term "eosinophilic granuloma of bone" has been widely accepted for a peculiar destructive granulomatous lesion of bone. To 48 cases of eosinophilic granuloma of bone that have been collected from the literature 5 new cases are added. The majority of the patients have been men and the majority have also been under 20 years of age. Laboratory examination showed slight leukocytosis and occasionally eosinophilia. Roentgenographic examinations showed round, oval or irregular areas of decreased density. The lesions produced expansion of the bone in 5 cases and perforation of the cortex in at least 5 cases. Periostitis was observed in 14 cases, and 3 lesions had sclerotic margins. The early lesions appear cystic at gross examination, containing soft, friable, yellowish brown and red material. A variety of cells, including large numbers of eosinophils, are seen on microscopic examination, but the characteristic cell is a large mononuclear cell with granular cytoplasm. Treatment by surgical excision, curettage or irradiation has given good results.

Cortical Excisions for Relief of Intractable Pain.—Horrax performed excision of the postcentral cortex in 2 patients who had been unrelieved by other forms of surgical intervention for painful extremities and in 2 patients whose pain was of cortical or thalamic origin and, therefore, presumably would have been uninfluenced by procedures on the spinothalamic tract or the sympathetic system. In the 2 patients with causalgia and phantom limb pain, respectively, the cortical excisions were followed by transient relief only. In the 2 patients who had central pain, relief was complete in 1 during the remainder of his life (ten months). In the other relief had been complete in the contralateral leg (one year and ten weeks, postoperatively) and was complete in the hand and arm for five months following the excision.

Surgical Treatment of Mental Depression.—Van Wagenen says that it has been argued that the relief from states of depression or tension results from a division of fibers running between the frontal cortex and the thalamus. Whether it is necessary to divide all the other association pathways in the frontal lobe is still open to question. The author describes several cases which in his opinion support the belief that the bilateral division of the white fiber pathways between the basal ganglion and the frontal lobe cortex is sufficient to secure relief from states of mental depression and tension and that section of more white fibers may be unnecessary.

Perforation of Ulcer During Roentgen Examination.—Schilling reports the case of a man aged 72 in whom during fluoroscopy barium was observed to streak out to the right and the left of the duodenal cap and promptly outline the right lower boundary of the peritoneal cavity. At operation a large perforation, 1.5 cm. in diameter, was found on the anterior portion of the first part of the duodenum. Everywhere there were flecks and small collections of whitish material. It was impossible to remove barium without damaging the serosa of the intestines. Accordingly, as much of the free fluid was aspirated as possible and the perforation was closed. Coincident with the ability to tolerate and retain food, the patient began to improve clinically. At follow-up examinations he appeared well. Barium sulfate was injected into the peritoneal cavity of 3 dogs. An immediate widespread diffusion of barium was noted roentgenographically. The dogs were sacrificed at one and one-half month intervals. Postmortem examination showed dense fibrous adhesions. The local microscopic reaction was one of fibrous encapsulation, lymphocytic infiltration and phagocytosis of barium by macrophages.

Cancer of Thyroid.—Cattell thinks that the best means available for decreasing the incidence of malignant disease of the thyroid is the early removal of all discrete adenomas. Furthermore, by this method thyroid carcinoma will be discovered and removed in its earliest stage. Radical neck dissections are recommended for all patients with lateral aberrant thyroid. Removal of extensive malignant tumors of the thyroid, combined with tracheotomy and postoperative radiation therapy, should be carried out whenever possible. Thyroid cancer is curable in from 17 to 80 per cent of cases, depending on the grade or histologic type of malignant disease. These results warrant a more optimistic approach to the problem.

*Incidence of Ulcer in Hematemesis. E. H. Cluer.—p. 651.

Incidence of Ulcer in Hematemesis.—Cluer obtained radiographic confirmation of peptic ulceration in only 7 of 18 cases of hematemesis. All patients did well on a routine treatment and about five weeks of hospitalization. Three months later peptic ulceration could be confirmed by roentgenoscopy in only 7. Two others gave histories suggestive of peptic ulceration, but radiographic evidence was not obtained. The diet, rest in bed and medicines were probably responsible for healing the ulcer and subsequent negative films. Two further cases proved to be due to cirrhosis of the liver, the hematemeses possibly being the result of ruptured esophageal varices or congestion consequent on portal obstruction. One patient had hypertension with severe epistaxis, and some of his hematemesis probably was caused by swallowed blood. The remaining 6 patients had no history of dyspepsia and were perfectly fit up to or just before the time of hematemesis. In all these cases a later x-ray film revealed a perfectly normal stomach and duodenum.

Influenza B in 1945-1946.—Dudgeon and his associates say that after influenza probably due to virus B appeared in the Netherlands and Belgium in December 1945 a moderately extensive outbreak of a mild influenza appeared in Britain in January. Serologic evidence indicated that 34 per cent of the cases were due to influenza virus B, but since it is known that not all cases of B virus infection show a specific serologic response it is likely that virus B was the major cause of the outbreak. Ferrets did not show a febrile reaction when inoculated with 1946 B viruses, but strains were successfully established by amniotic inoculation of fertile eggs. They were serologically rather distinct from the standard (Lee) B virus but very closely related to two strains isolated in Australia in November 1945.

Plummer-Vinson Syndrome.—Savilahti reports 2 cases of Plummer-Vinson syndrome from the medical and pathologic department of the Kivelä Hospital in Helsinki: 1. A woman aged 77 had nausea and difficulty in swallowing solid food for several years. Her skin was extremely pale, with a yellow tinge. The mucous membranes also had a pale appearance. The tongue was smooth and shiny. The severe hypochromic anemia and dysphagia disappeared after four months of iron therapy. In the wall of the esophagus below the aortic arch a dilatation and a diverticulum were revealed on x-ray examination. These changes were still observed when dysphagia had disappeared after treatment. 2. A woman aged 71 had difficulty in swallowing solid food for several years before admission. When admitted she had right lobar pneumonia. There were rhagades at the corners of the mouth and leukoplakia in the mucosa of the lower lip. The tongue was dry, smooth and atrophic. She died of pneumonia. Necropsy revealed that the tongue was nearly entirely depapillated. Leukoplakia was present in the wall of the larynx. The epithelium of the esophagus showed local atrophy. Signs of chronic inflammation were also noted. The muscular wall was atrophic about the middle of the esophagus, and the connective tissue was infiltrated by round cells. Dysphagia in this condition is evidently due to muscular degeneration in the esophagus. It is also possible that some of the diverticula and dilatations of the esophagus arise from similar causes, as they probably did in case 1.

Toxic Diffuse Goiter in Men.—Larsen has noted a pronounced increase in recent years in the number of cases of toxic diffuse goiter in the medical department B of Rigshospital in Copenhagen. The increase has been relatively greater in men. An increase in the number of "masked" cases of toxic diffuse goiter may be considered responsible for the relatively greater incidence of this disease in men. Cases of toxic diffuse goiter may be described as masked cases in which the characteristic symptoms such as the enlargement of the thyroid, exophthalmos and the basedowian habitus are absent or are not pronounced, while less characteristic symptoms such as loss of weight, cardiac symptoms, gastrointestinal complaints and glycosuria predominate and suggest a different condition, or in which the typical symptoms are masked by symptoms of an associated pathologic condition. In 174 cases of toxic diffuse goiter the condition was masked in 26 of 81 men and in 11 of 93 women. A difference was not observed in the average age of the men and women on admission, but the age distribution showed a characteristic difference between the two sexes: for the men the maximum incidence was found between the ages of 40 and 49, while the incidence among the women was distributed evenly among the ages of 20 and 59 years.

Book Notices

Handbook of Diet Therapy. Written and compiled by Dorothea Turner for the American Dietetic Association. Cloth. Price, $2. Pp. 112. University of Chicago Press, 5750 Ellis Ave., Chicago 37, 1946.

This handbook on therapeutic diets has been prepared for the Diet Therapy Section of the American Dietetic Association. It represents a new and very sound technic for the selection of special type diets in which the diet is evaluated on the basis of the patient's nutritional needs, the method of planning is simplified and practical considerations of its acceptability to the patient are taken into account. The terminology and classification of therapeutic diets are simplified as well. These highly desirable objectives have been attained by the rational expedient of adopting the basic normal diet pattern which meets the recommended dietary allowances in all respects to the special therapeutic need. In following this plan, substitutions of appropriate types or forms of foods may be made in the normal pattern without sacrificing nutritional adequacy. This approach to dietary treatment removes the mysticism, faddism and confusion which have reigned for so long.

In the handbook there are some twelve normal-adapted diets outlined, as well as others for conditions of special nutritional requirements as in pregnancy, lactation and childhood. For each type a discussion of the objectives of the diet is given, and suggestions are given for accomplishing some changes without actual revision of the food pattern. A tabular chart is shown for each special type diet giving the nutritive contribution of each food item with the totals to demonstrate the nutritional completeness. These dietary patterns found in the handbook are not menu lists, since they consist of an outline for one day's food intake. They provide adequate essential nutrients but not necessarily adequate calories. Menu variety must be afforded by making substitutions and additions from the tables of food composition found in the appendix, to meet the needs of individual patients.

Since the book presents an approach to diet therapy which is new and in full accord with modern nutritional thought, it should be familiar to every one concerned with the prescribing of diets. It can be recommended as a reference book which has much practical information of value to the physician.

Allergy. By Erich Urbach, M.D., Chief of Allergy Department, Jewish Hospital, Philadelphia, and Philip M. Gottlieb, M.D., Associate in Allergy Department, Jewish Hospital, Philadelphia. Second edition. Fabrikoid. Price, $12. Pp. 968, with 412 illustrations. Grune & Stratton, 381 4th Ave., New York 16, 1946.

This is an excellent reference book on allergy for the physician who has had some fundamental training in allergy or for the specialist in allergy or related fields. It is not to be recommended for the physician whose training in allergy has been limited. The present edition is a thorough revision of the first. The change in format through the use of a double column makes it more easily read. The new subjects added are not too important in allergy. The improved organization of the general subject matter and the enlargement of these subjects is indicated by the use of over thirty-three hundred references—a thousand more than in the previous edition. The value of this work is that it covers thoroughly the entire field, not just the respiratory conditions.

Many of the faults of the first edition are unfortunately still carried over into the revised work. First is the insistence of the authors on their own particular terminology for immune and allergic reactions. Such cumbrous and unfamiliar terms as pathergy, parallergy, metallergy, allergization, deallergization and skeptophylaxis are used throughout the text. These have not been accepted in the American literature despite the efforts of both authors in various publications.

Despite the fact that "propeptan" desensitization has not been found of value by American workers, the authors recommend protein digests as their first choice for the treatment of food and inhalant allergy. Other methods of therapy are fully described, but it would take an experienced worker in allergy to discriminate between usually accepted methods and those strongly recommended by the authors.

While most of the illustrations are well chosen and generally clear, some are pointless. The pictures of a tuberculin syringe, of two scarifiers and of two types of boxes containing "diagnostic sets" belong in a sales catalogue rather than in a reference book. Redundance of illustration is exemplified by at least eight photographs of angioneurotic edema and eleven of urticaria due to different agents. No great difference in morphologic appearance is seen in these photographs.

Good clinical judgment is absent in some of the recommendations for pollen therapy. The "propeptan" prescription for the oral pollen includes not only the two ragweeds and cocklebur but goldenrod and dahlia as well (p. 556). Similarly (p. 884) the authors include in their test sheet for pollens a number of materials that are either rare as causes of symptoms or are typical insect borne pollens. Thus the pollen of pine (1 case reported in the entire literature) is listed for testing among the tree pollens; dahlia, daisy, sunflower, corn and crab grass among the pollen of the late summer season, and dandelion, oat, rye and wheat among the pollens of the early summer season.

If these and similar peculiarities and errors of this book were discounted by the experienced reader he would find this a well organized, up-to-date reference book. The general practitioner or the beginner in allergy would hardly find this a suitable book unless it was supplemented by a more orthodox textbook.

Stedman's Practical Medical Dictionary of Words Used in Medicine with Their Derivation and Pronunciation Including Dental, Veterinary, Chemical, Botanical, Electrical, Life Insurance and Other Special Terms; Anatomical Tables of Titles in General Use, the Terms Sanctioned by the Basle Anatomical Convention; the New British Anatomical Nomenclature; Pharmaceutical Preparations Official in the U. S. and British Pharmacopœias or Contained in the National Formulary; and Comprehensive Lists of Synonyms. Edited by Norman Burke Taylor, M.D., F.R.S., F.R.C.S., in collaboration with Allen Elsworth Taylor, D.S.O., M.A. Sixteenth edition with Etymologic and Orthographic Rules. Fabrikoid. Price, $7.50 with thumb index (without index $7). Pp. 1,291, with illustrations. William Wood & Company (Division of Williams & Wilkins Company), Mount Royal and Guilford Aves., Baltimore 2, 1946

The sixteenth edition of Stedman's Practical Medical Dictionary has been edited by Dr. Norman B. Taylor of the University of Toronto. He points out in the preface that hundreds of new words have been added, many of which pertain to war medicine, tropical diseases and physiologic and biochemical topics. Dr. Taylor did not consider it desirable, however, to include all the names of new proprietary drugs that have evolved in recent years. The book is prefaced with an excellent essay on medical etymology indicating the origin of most medical terms from Greek and Latin roots. The volume is dated by its failure to include the words streptomycin, patulin and subtilin, recently announced antibiotic molds. Testosterone is said to be obtained from testicular tissue, and there is no reference to synthetic substances. Although new proprietary drugs are not included, there are still references to such "old timers" as Brown-Séquard's antineuralgic pill and Gray's glycerin tonic. The dictionary has had a long and useful career and provides much useful information such as is required by those who know how to use dictionaries.

Actions and Uses of Drugs: A Textbook for Nurses. By Windsor C. Cutting, M.D., Professor of Therapeutics, Stanford University School of Medicine, Stanford University, California. Cloth. Price, $3. Pp. 326, with 27 illustrations. Stanford University Press, Stanford University, California, 1946.

This textbook, designed for nurses, marks a distinct departure from the usual approach to pharmacology and materia medica. Too often the textbooks in this field attempt to present so much detail that the student nurse either grasps none of it or else becomes so impressed with her apparent grasp of the subject that she considers herself an expert on drugs. Nurses should neither compound nor prescribe, but they should have an understanding of the drugs they administer under the direction of the physician. This textbook is ideally adapted to provide such an understanding without burdening students with unnecessary detail or encouraging them to become "little physicians." The book opens with a clear discussion of the types of therapy, the difference between pharmacology and pharmacy, the sources of information about drugs and the manner in which the actions of drugs are studied. It proceeds to a consideration of locally acting drugs followed by a description of those administered for their systemic actions. For each drug a brief description of its source, mode of action, principal uses and ordinary dosage is given. The text is well illustrated with simple and readily understandable diagrams. This volume can be heartily recommended for use in all nursing schools.

Diagnostic Examination of the Eye: Step-by-Step Procedure. By Conrad Berens, M.D., F.A.C.S., Professor of Clinical Ophthalmology, Columbia University, New York, and Joshua Zuckerman, B.Sc., M.D., C.M., Instructor in Ophthalmology, New York University, New York. Fabrikoid. Price, $15. Pp. 711, with 410 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5, 1946.

This describes the various procedures in conducting a complete and thorough eye examination and is of value chiefly for the young specialist. The first 38 pages are devoted to history taking and presents record forms. Each step from inspection through the use of special instruments is described and the use of the instruments given in detail. The various diseases and anomalies to be found in each anatomic segment of the eye, adnexa and nervous pathways are mentioned. No differential diagnosis or treatment is attempted. In part III eye standards for the military, federal, civil service, aviators and motor vehicle drivers and classification of blindness is given. While most instruments are mentioned and their use is described, the authors do not indicate preference for any given instrument. Less than half a page is devoted to the Nagel Anomaloscope, the only really accurate method of testing color vision. The book can in no way be considered a textbook of ophthalmology, since anatomy, pathology, differential diagnosis, therapy and surgery are omitted. It will serve the purpose for which it was intended, namely as a guide for the routine complete ophthalmic examination and a ready reference to the use of instruments for supplemental or more detailed ocular study.

Inheritance of Harelip and Cleft Palate: Contribution to the Elucidation of the Etiology of the Congenital Clefts of the Face. By Poul Fogh-Andersen. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. *Translated from the Danish by Elisabeth Aagesen. Paper.* Pp. 266, with 75 illustrations. Nyt Nordisk Forlag Arnold Busck, Kjøbmagergade 49^1, København K, 1942.

The work reported in this monograph was carried out in Denmark from 1939 to 1941. It constitutes an extensive study of the genetic factors related to harelip and cleft palate. From the large Danish material it was concluded that 25 per cent of those affected have harelip alone, 50 per cent have harelip and cleft palate, and 25 per cent cleft palate alone. The author states that, contrary to the prevailing view, there are two different malformations without genetic connection, namely harelip with or without associated cleft palate, and isolated cleft palate. The former, he believes, is hereditary in most cases, whereas in isolated cleft palate there is probably a considerable admixture of nonhereditary cases. Although a chapter on theories and etiology of cleft palate is included in the monograph, reference is not made to the possible role of German measles during early pregnancy. This monograph will henceforth be required reading for all those conducting studies on the genesis of harelip and cleft palate.

The Normal Encephalogram. By Leo M. Davidoff, M.D., Professor of Clinical Neurological Surgery in the College of Physicians and Surgeons, Columbia University, New York, and Cornelius G. Dyke, M.D. Second edition. Cloth. Price, $5.50. Pp. 232, with 155 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1946.

Since the first edition, now long out of print, was published in 1937 the junior author, a radiologist, has died and Dr. Davidoff, a neurosurgeon, is alone responsible for the second edition. The general character of the book in the new printing remains unchanged, but old illustrations have been replaced by new, the text is extended by eight pages and the bibliography has been revised and brought up to date. Revision has been expertly done, and the new material adds greatly to the value of the book. It is hoped that the companion volume mentioned in the preface, "The Abnormal Encephalogram," half finished at the time of Dr. Dyke's death in 1943, will be prepared shortly for publication. Such a volume, urgently needed and long anticipated by the medical profession, would be an ideal companion to "The Normal Encephalogram."

Textbook of Pediatrics (Mitchell-Nelson). Edited by Waldo E. Nelson, M.D., Professor of Pediatrics, Temple University School of Medicine, Philadelphia. With the Collaboration of Forty-Nine Contributors. Fourth edition. Cloth. Price, $10. Pp. 1,350, with 333 illustrations. Philadelphia & London: W. B. Saunders Company, W. Washington Square, Philadelphia 5, 1946.

This textbook of pediatrics comes as a memorial to Dr. A. Graeme Mitchell, who died in 1941. Forty-nine contributors under the editorship of Dr. Waldo E. Nelson take the responsibility for the book. It is a successor to the Griffith and Mitchell textbook. The work has been completely rewritten and brought together in a single volume using the double column method of presentation. Various sections of the work cover every aspect of pediatrics, beginning with the care and evaluation of the well child and then taking up the sick, the newborn, the premature, nutritional disturbances, malformations, infectious diseases and so on. The infectious diseases are grouped as bacterial, spirochetal, virus, rickettsial, mycotic and parasitic conditions. The broadening of the group of virus diseases is significant. The selection of authors and the quality of the material are of an exceedingly high order. The material is presented in succinct form, there are many excellent illustrations, and suggested bibliographies supplement each of the contributions. An elaborate index adds to the usefulness of this excellent book.

The New Science of Surgery. By Frank G. Slaughter, M.D. Cloth. Price $3.50. Pp. 286. Julian Messner, Inc., 8 W. 40th St., New York 18, 1946.

Dr. Slaughter is the author of at least five novels. He has been a practicing surgeon both in civil life and under military conditions. He writes easily, so that his book is a fine contribution to better public information regarding the accomplishments of modern surgery and the investigations and discoveries which led to those accomplishments. There are excellent chapters on surgery of the chest and the heart, on the use of refrigeration and on brain surgery. Later chapters consider burns, plastic surgery and psychosomatic surgery. Of special interest at this time are the final chapters entitled "Is Surgery Too Expensive?" and "Medicine in the Postwar World." The final chapter is a reprint of an article written by the author in 1940 in which he proposes a system of medical care involving clinical practice by groups with government support where necessary and with a sort of combined compulsory and voluntary health insurance system.

Notes on Nursing: What It Is, and What It Is Not. By Florence Nightingale. A facsimile of the first edition published in 1860 by D. Appleton and Co., New York. With a foreword by Virginia M. Dunbar, Dean, Cornell University, New York Hospital School of Nursing and Director of the Nursing Service, New York Hospital, New York City. Cloth. Price, $2. Pp. 140. D. Appleton-Century Co., Inc., 35 W. 32d St., New York 1, 1946.

Notes on Nursing: What It Is, and What It Is Not. By Florence Nightingale. [Facsimile of first American edition published in 1860 by D. Appleton and Co., New York.] Cloth. Price, $1.35. Pp. 79. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5, 1946.

These are two editions of "Notes on Nursing: What It Is and What It Is Not," by Florence Nightingale. The two publishers have simultaneously produced facsimiles of this book by Florence Nightingale. The book by D. Appleton-Century Company has a preface by Virginia M. Dunbar and is a facsimile of the first American edition which was published in 1860 by Appleton and contains the Appleton advertisements that were then published in the end of the book. The book by Lippincott has a foreword by Annie W. Goodrich and is a facsimile of the first London edition printed in 1859, including the advertisements of the publisher at the end of the book.

The Drama of Sex. By James Lincoln McCartney, M.D., F.A.C.P., Commander (MC) U.S.N.R. Cloth. Price, $2.50. Pp. 147, with illustrations. Stratford House, Inc., 52 Vanderbilt Ave., New York 17, 1946.

Here is another book of advice to the lovelorn in modern dress. Its author has put under his name on the title page sixteen lines of description of himself which indicate that he ought to know what he is talking about. The book follows standard lines in its descriptions of the tissues involved in sex and their functions. It attempts to explain psychosexual development but must perforce get into the terminology of freudian concepts. In his suggestions as to sexual initiation following marriage the author becomes lyrical without abusing the facts. There are chapters on marriage adjustment and pregnancy which follow standard lines and a final chapter on planned parenthood which tells most of what is now known on birth control.

The Human Ear in Anatomical Transparencies. Descriptive Text by Stephen L. Polyak, M.D., Professor of Anatomy, University of Chicago, Chicago. Anatomical Transparencies and Illustrations by Gladys McHugh, Medical Illustrator, University of Chicago Clinics. Anatomic Preparations by Delbert K. Judd, M.D., Assistant Professor Otolaryngology, University of Chicago. Published under the auspices of Sonotone Corporation. Fabrikoid. Price, $10.50. Pp. 136, with 83 illustrations. T. H. McKenna, Inc., 882 Lexington Ave., New York 21, 1946.

The use of anatomic transparencies in the teaching of the anatomic relations between the structures has now been well established. The book on the human ear is an elaborate production requiring several years for its accomplishment. Specimens were expertly dissected as a basis for the colored paintings by Miss Gladys McHugh. Many of the faculty of the University of Chicago School of Medicine cooperated in the preparation of the manuscript. The section on the evolution of the ear and hearing is a fascinating addition to the strictly anatomic text. No better guide to the structure of all the organs involved in hearing is thus far available. An extensive bibliography completes the work.

Xenopus Laevis: A Bibliography. Compiled by H. Zwarenstein, M.A., D.Sc., F.R.S.S.Af., N. Sapeika, B.A., M.B., Ph.D., and H. A. Shapiro, B.A., Ph.D, M.B. Cloth. Price, 10s. Pp. 51. Published for the University of Cape Town by the African Bookman, P. O. Box 3115, Cape Town, S. A., 1946.

This little volume covers the entire literature on Xenopus levis, the South African clawed frog. Before 1933 this animal was used for experimental physiology by Jolly and Hogben. In 1933 Shapiro and Zwarenstein were the first to report on the use of Xenopus levis as a test animal for the diagnosis of human pregnancy. Since then many publications have appeared all over the world and therefore this bibliography was thought to be useful. It is a most complete piece of work and should be of value to all laboratory workers interested in the use of this amphibian. The literature on the history of anatomy, physiology, reproduction, breeding, pharmacology, bacteriology and parasitology of this frog is covered.

Autour du problème du cancer. Par le Docteur J. M. Montpellier, professeur d'anatomie pathologique et d'oncologie humaine et comparée a la Faculté mixte de médecine et de pharmacie d'Alger. Ouvrage honore d'une subvention du gouvernement général de l'Algérie. Paper. Pp. 337, with 12 illustrations. Librairie Ferraris, 43 rue Michelet, Algiers, 1944.

The author discusses the more general aspects of the cancer problem. Attention is given various biologic concepts concerning the etiology of cancer, and then in turn the precancerous state, the role of trauma and carcinogenesis in general are discussed. Some consideration is given to the question of metastasis and also to the spontaneous regression of cancer. Principles of therapy are presented in a generalized manner. No attempt is made to discuss the various forms of neoplasia individually. The entire book deals in generalities, with little specificity. Mention is made of recent experimental progress, and a plan for individual and mass prophylaxis is presented.

Infiltrazione novocainica del plesso celiaco: Applicazioni terapeutiche. Dal Dott. Renato Rossi, specialista in chirurgia generale, Istituto di clinica chirurgica e terapia chirurgica generale della Università di Torino. Prefazione del Prof. A. M. Dogliotti. Paper. Pp. 79. Edizioni I. T. E. R., Industrie Tipografico Editoriali Riunite, Turin, 1945.

The preface by Professor A. M. Dogliotti is followed by an introduction and technical observations. The chapters that follow cover the therapeutic infiltration with procaine hydrochloride of the celiac plexus, the block with procaine of the celiac plexus as a modifier of secretion of epinephrine, arterial tonus and glycoregulation, the infiltration with procaine of the celiac plexus in renal diseases, the infiltration with procaine of the celiac plexus in visceral apoplexies, the infiltration with procaine of the celiac plexus in acute abdominal syndromes and the infiltration with procaine of the celiac plexus in the practice of anesthesia. A bibliography follows.

Diseases of the Basal Ganglia and Subthalamic Nuclei. By D. Denny-Brown, M.D., C.H.B., Dr. Phil., Professor of Neurology, Harvard University, Boston. Edited by Henry A. Christian, A.M., M.D., LL.D. [Reprinted from Oxford Loose-Leaf Medicine with the Same Page Numbers as in That Work.] Cloth. Price, $2.50. Pp. 261-302 (74). Oxford University Press, 114 Fifth Ave., New York 11, 1946.

This brief monograph is a reprint from Oxford Loose-Leaf Medicine. It presents in readily available form the symptoms, signs, pathology and available treatment of the more common disorders of this part of the nervous system. These include the various forms of parkinsonism, hepatolenticular degeneration, dystonia musculorum deformans, double athetosis and Huntington's chorea. The confusion and incompleteness which characterize the discussions of the anatomy and physiology of this region are a measure of our ignorance in this field. One of the large neurologic problems which awaits thoroughgoing investigation and elucidation is the structure and function of the basal ganglions in primates. It is to be hoped that in the not too distant future we shall not have to be content with so imperfect a presentation as present day circumstances impose on us.

Introduction to Clinical Neurology. By Gordon Holmes, M.D., F.R.S. Cloth. Price $4. Pp. 183, with 37 illustrations. William Wood and Company, Mt. Royal & Guilford Aves., Baltimore 2, 1946.

Outstanding teachers in any field are rare, and in a limited field like clinical neurology are even more uncommon. Gordon Holmes is one of the world's most justly famous teachers of his subject. Many an American has been fortunate enough to benefit by a clerkship under Dr. Holmes at the National Hospital for Nervous Diseases at Queen Square and to enjoy weekly ward rounds with him. To those this book will rekindle many fond memories. Here set forth in concise clear statements, which have always characterized the English clinical neurologists, are the many things which Gordon Holmes by word and deed taught us. This book will prove valuable, as well as enjoyable, to every one; but the young student of neurology in particular will benefit from this excellent introductory textbook by the master of the subject. It is not a textbook of clinical neurology. Disease entities, diagnosis and treatment are not discussed. This is the proper approach to the neurologic patient and his disease. Here are presented the significance of the signs and symptoms of neurologic dysfunction. The reader is told how a neurologic examination should be conducted and how to interpret the results. This is and will continue to be one of the classics of neurology.

The Adventures of Jimmy Martin, Stowaway. By David Polowe. Cloth. Price, $2. Pp 160. Colt Press, 549 Main St., Paterson 3, New Jersey, 1946.

This book is an interestingly written account of a 14 year old boy who stowed away on an American ship and ran into adventures with spies, German submarines and the like. It does not contain anything of medical interest other than what the shipping articles provide regarding supplies of food to the enlisted men.

Threescore Years and Ten: A Narrative of the First Seventy Years of Eli Lilly and Company, 1876-1946. By Roscoe Collins Clark. Privately printed. Cloth. Pp. 132, with illustrations. Eli Lilly and Company, Indianapolis 6, 1946.

For those who are interested in the growth of the modern drug industry this book will provide an informative outline of one member. Obviously the volume will have the greatest appeal for those who are members or friends of members of the Lilly organization.

Doctor Destiny. By Edward R. Janjigian. Fabrikoid. Pp. 211. Edinburg, Indiana: The Author, 1946.

Doctors who undertake fiction are confronted with the double task of competence in both medicine and authorship. This is a novel about a schizophrenic who wanted to be a doctor which unfortunately does not meet the standard of competence in novel construction and reproduction of dialogue.

Report of a Better Breakfast Project Week of January 14, 1946: A Community Program Sponsored by The Council on Nutrition of The Public Health Federation of Cincinnati and Hamilton County, Ohio. Paper. Pp. 152, with illustrations. Cincinnati: Public Health Federation; Chicago: Cereal Institute, Inc., 1946.

This is a report on a community project in which twenty-eight agencies and commercial groups participated. Methods are briefly described and the printed material used is included.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DIFFERENTIAL DIAGNOSIS OF GLYCOSURIA

To the Editor:—Please answer the following questions on the differential diagnosis of glycosuria: 1. If a single urine specimen shows sugar and a blood sugar determination at the same time is 170 mg. per hundred cubic centimeters or over, can a diagnosis of diabetes mellitus be made regardless of when or what the patient has eaten? 2. Is a diagnosis of "alimentary glycosuria" possible? If glycosuria appears after eating and the blood sugar is normal, is that not renal glycosuria? If glycosuria appears after a meal and the blood sugar is above an arbitrary figure, such as 170 mg. per hundred cubic centimeters, is that not true diabetes? 3. If a single examination reveals glycosuria but a glucose tolerance test is normal without glycosuria, would the original glycosuria be called "emotional glycosuria"?

M.D., New York.

Answer.—1. It would be hazardous to make a diagnosis of diabetes mellitus on the basis of a single blood sugar figure, particularly if the blood has been drawn after eating. Transient changes in blood sugar concentration not due to diabetes, as well as technical errors in blood analysis, are altogether too common to permit a diagnosis to be made on such arbitrary grounds.

2. A diagnosis of "alimentary glycosuria" does not mean much. The findings which lead to this diagnosis often indicate early diabetes mellitus, but more data than a single blood sugar determination are necessary before a diagnosis of diabetes mellitus can be made. Persistent glycosuria accompanied by consistently normal blood sugar levels may be accepted as renal glycosuria. The sugar must be identified as glucose, the blood sugar must be proved to be normal even after dietary attempts to raise it, and other criteria must be satisfied before a diagnosis of renal glycosuria is permissible. (The answer to the second question in 2 is given in 1.)

3. The accidental discovery of sugar in the urine followed by a normal glucose tolerance test might be due to emotional causes. Certainly emotion is a common cause of transient glycosuria and hyperglycemia. However, early diabetes mellitus which is so mild that sugar fails to appear on administration of a standard glucose meal cannot be excluded. Experience not uncommonly finds true diabetes following normal glucose tolerance tests. The passage of time with repeated attempts to prove or disprove the existence of diabetes is the only safe diagnostic method to apply in doubtful cases. It is also possible for other melliturias, such as pentosuria, to appear transiently and be followed by a normal glucose tolerance curve. Hyperthyroidism and certain drugs cause transient glycosuria. Emotional glycosuria is therefore only one of a number of conditions which might exist, including diabetes mellitus, when the discovery of sugar in the urine is followed by a normal glucose tolerance curve.

CATARACT SURGERY IN PATIENT WITH HEAD TREMOR

To the Editor:—A man aged 67 who was operated on for a senile cataract of the right eye six months ago with good results has a head tremor due to arteriosclerosis of the basal ganglions. He is otherwise in good health. Would it be advisable to operate on the left eye when the cataract becomes mature? If so should the lens be removed in a two stage operation or should only iridectomy be performed to prevent possible glaucoma?

M.D., Pennsylvania.

Answer.—Since the result of operation on the right eye was good there would seem to be no contraindication to performing a similar procedure on the left. A one stage operation is generally considered preferable, and with present day methods of intracapsular extraction and corneoscleral sutures most complications are avoided.

DYSTONIA MUSCULORUM DEFORMANS

To the Editor:—Two sisters aged 24 and 22 years were perfectly well until ten years ago, when they became bedridden. A diagnosis of dystonia musculorum deformans was established two years ago. They were treated with 36 grains (2.3 Gm.) of quinine per day for a while. The disease is gradually getting worse. Please suggest further treatment.

M.D., New Jersey.

Answer.—There is no accepted form of successful treatment for dystonia musculorum deformans.

PROBABLE GASTROINTESTINAL LESION

To the Editor:—A man aged 55, a plumber, five years ago developed pain in the back, generalized weakness and vague abdominal distress for one month. Since then he has had the following symptoms of varying severity: (1) periods of persistent epigastric soreness with occasional severe distress relieved by milk, occurring in midafternoon but never in the morning or evening; (2) loss of 20 pounds (9 Kg.) weight the first year of illness and 5 pounds (2.3 Kg.) since then (the patient now weighs 141 pounds, or 64 Kg.); (3) gradual development of numbness in the fingers and toes and difficulty in buttoning his clothing; (4) increasing weakness, which caused him to stop work six months ago. Six weeks ago the patient was hospitalized because of a sudden severe gastrointestinal hemorrhage, manifested by a copious tarry stool and hematemesis. Transfusion was required. The hemorrhage occurred after two days of back pain for which the patient had taken several doses of acetylsalicylic acid and two strong laxatives. Since discharge from the hospital gastrointestinal symptoms have been absent. After an initial milk and alkali ulcer diet the patient now eats everything without distress. Physical examination in 1942 revealed moderate deep tenderness in the epigastrium, absent patellar, achilles and abdominal reflexes, negative Babinski sign, positive Romberg's sign, no ataxia and questionably reduced vibration sense. The blood pressure was 95-100/70. Present findings are the same with added evidence of moderate weight loss. There are no skin or tongue changes. Complete gastrointestinal roentgenograms eight months ago were negative and an upper gastrointestinal study four weeks after the hemorrhage was also negative. X-ray examination of the lumbodorsal spine was negative except for increased calcified densities in the mediastinum and adjacent lung fields. Fluoroscopy of the chest was negative. Blood Kahn tests in 1941 and 1946 were negative. Spinal fluid examination in 1946 showed leukocytes 2, erythrocytes 58, protein 51 mg. per hundred cubic centimeters, Kahn test negative, colloidal gold test 0000000000. Ewald gastric analysis showed no free acid, total acid 11 and no blood. Urinalysis was negative on six occasions. Blood chemical studies revealed the icterus index 7, sugar 102 mg. per hundred cubic centimeters, chlorides 468 mg. per hundred cubic centimeters, cholesterol 286 mg. per hundred cubic centimeters, calcium 11 mg. per hundred cubic centimeters. Blood counts in 1941 revealed erythrocytes 4,700,000, hemoglobin 90 per cent, leukocytes 10,500; in December 1945 erythrocytes 5,100,000, hemoglobin 95 per cent, leukocytes 12,200, sedimentation rate 17 (Westergren); April 1946 (two weeks before hemorrhage) erythrocytes 5,300,000, hemoglobin 17 Gm., leukocytes 9,900, erythrocyte volume 50, sedimentation rate 12; in May 1946 (one day after hemorrhage) erythrocytes 3,200,000, hemoglobin 66 per cent, with no change after three weeks' hospitalization; in June 1946 erythrocytes 4,000,000, hemoglobin 77 per cent, sedimentation rate 25. (The last erythrocyte count and hemoglobin estimation were not influenced by three injections of liver extract.) The differential white blood count has always been normal. Poikilocytes and young cells have never been found in the smears. Does this patient have an organic gastrointestinal lesion plus pernicious anemia with posterolateral sclerosis as an independent disease? Can pernicious anemia be diagnosed with cord changes but without true anemia at any time over four years? Is liver indicated in this case? What further studies are indicated?

M.D., Colorado.

Answer.—Tarry stools and hematemesis followed by a definite drop in the red blood cell count and hemoglobin are strong evidence in favor of an organic gastrointestinal lesion, most likely in the esophagus, stomach or duodenum. It is not always easy to demonstrate roentgenologically the source of a hemorrhage from the upper gastrointestinal tract such as this patient presumably had. In such cases repeated roentgenologic examinations are definitely indicated in search of a demonstrable lesion such as peptic ulcer in the stomach or duodenum, esophageal varices, gastric carcinoma or diaphragmatic hernia. At times the probable source of the hemorrhage can best be found gastroscopically as in some cases of hypertrophic gastritis or gastric polyp. Gastroscopy is, of course, contraindicated in the presence of esophageal varices.

The question of whether this patient has achlorhydria is important in relation to the various diagnostic possibilities. The presence of free acid would not support the diagnoses of pernicious anemia, typical subacute combined degeneration of the cord or a combination of the two. On the other hand, the persistent absence of free acid would not be compatible with a diagnosis of peptic ulcer. It should be noted, however, that the most reliable and potent method known of stimulating gastric secretion is by means of the subcutaneous injection of histamine. Unless the evidence of achlorhydria is based on several histamine gastric analyses and it is known that the tip of the tube is in the lower portion of the stomach during the gastric aspirations (this can be checked fluoroscopically), the results cannot be considered as proof of achlorhydria.

Subacute combined degeneration of the cord without the blood and bone marrow findings or pernicious anemia occurs and is a recognized clinical entity. The treatment frequently recommended is liver therapy employing dosages similar to those used in the treatment of pernicious anemia. Massive doses of liver have also been recommended. The value of liver therapy in subacute combined degeneration of the cord without anemia has, however, been questioned and there is evidence to indicate that it does not alter the course of the disease.

On the basis of the information given, it seems unlikely that the patient could have tabes dorsalis. It should be emphasized, however, that the serologic reactions and spinal fluid findings may both be normal at times in some cases of tabes and that in such cases the history, physical findings and the results of subsequent spinal fluid examinations may be of diagnostic significance. In the absence of Argyll-Robertson pupils or other suggestive pupillary changes such a diagnosis would hardly be tenable. But, in the presence of signs of posterolateral sclerosis and abnormal pupillary reflexes, tabes becomes a definite probability despite normal serologic and spinal fluid findings.

The neurologic findings, however, do not appear to offer a satisfactory explanation for the hematemesis, and further investigation into this phase of the problem seems indicated as outlined. With regard to the question of liver therapy, there seems to be no clearcut indication for its use in this case.

HEPATOMEGALY AND PORTAL OBSTRUCTION IN DIABETIC CHILD

To the Editor:—A girl aged 6½ years, diabetic for eighteen months, during the last four months has developed dilated veins over the feet, thighs and abdomen, more severe on the right side. The liver is palpable two fingerbreadths below the costal margin and is slightly tender. The stools are of large diameter but otherwise normal in appearance and frequency. Hemoglobin, erythrocytes, leukocytes and the differential leukocyte count are normal. The child has gained 3 pounds (1,360 Gm.) and grown 1 inch (2.5 cm.) in the last six months. No jaundice, ascites, edema or digestive disturbances have been noted. She is apparently happy and normally energetic. The diabetes is controlled by a diet of carbohydrate 150, protein 70, fat 75 and insulin regular 12 units and protamine zinc 6 units before breakfast. The diet is supplemented by 500 mg. of methionine and 200 mg. of choline daily. What diagnostic and/or therapeutic procedures are suggested?

M.D., Wisconsin.

Answer.—The child referred to in this query presents a diagnostic problem in relation to the enlarged tender liver and the dilated veins over the feet, thighs and abdomen, more severe on the right side. Occasionally in diabetes a rise in blood lipids may occur accompanied with hepatomegaly and sometimes splenomegaly. When the enlarged liver of such patients has been examined it has been found to contain excess fat. It might be of interest in this case to examine the blood lipid content. In the absence of jaundice other possible causes of liver enlargement such as abscess, cyst and neoplasm should be considered, as well as leukemia, amyloidosis and the lipid storage diseases. However, in the presence of a frank diabetes it can be assumed that these other conditions for hepatic enlargements have been ruled out. Whatever condition is causing the liver hypertrophy may also be causing a portal obstruction, which would be evidenced by the venous dilatation as described. In all probability, therefore, diagnostic procedures should be focused on establishing a fatty liver as the cause of the liver enlargement and the venous dilatation through portal obstruction.

In the absence of "lipotropic" factors, fat tends to accumulate in the liver. Choline is an important lipotropic factor and is chiefly supplied from the pancreas. Another factor recently described by Dragstedt under the term "lipocaic" is furnished by the pancreas. Methionine, an amino acid containing sulfur, is also said to have lipotropic action.

Therapeutically it might be wise to decrease the fat intake and increase the protein and carbohydrate and insulin dosage for a period in an attempt to decrease the size of the liver and relieve the venous dilatation. Dosage of choline could also be gradually increased on the theory that the pancreas is unable to furnish the required amount for preventing fatty infiltration. The dose of choline could be gradually increased to as much as 2 Gm. daily. As the liver is the storehouse for certain of the vitamins, an ample supply of the multivitamin preparations seems indicated.

GENERALIZED VISCEROPTOSIS

To the Editor:—Please discuss the treatment of generalized visceroptosis in a woman aged 30.

Louis Goldberg, M.D., Bronx, N. Y.

Answer.—The clinical significance of visceroptosis, whether general or more localized in nature, such as so-called right-sided or midline ptosis, is a controversial matter. As the result of authentic clinical observations and anatomic research in the last few decades, leaders in the medical profession have become more and more skeptical and even entertain serious doubts as to whether such a diagnosis as enteroptosis, gastroptosis or coloptosis is warranted. For a more detailed discussion of the subject in this respect consult Nelson's New Loose-Leaf Medicine **5**:329, 1942. To those who entertain an opposite point of view, information concerning corrective exercises and treatment of this condition will be found in the articles by Martin (*Surg., Gynec. & Obst.* **15**:150 [Aug.] 1912), Anderson (*M. Times* **65**:247 1937) and Spiesman (*Rev. Gastroenterol.* **7**:218 [May-June] 1940).

TESTS FOR BARBITURATES AND EFFECTS OF PROLONGED USE

To the Editor:—1. What tests can be made to determine the presence of barbituric acid or barbituric acid products in the blood? 2. Has the prolonged use of luminal or phenobarbital or barbituric acid any effect on sexual function in men?

M.D., Massachusetts.

Answer.—1. The following method is satisfactory for estimating barbiturates in blood and also in urine. The compounds are extracted with chloroform, and cobalt acetate and isopropylamine are added. The reddish color is compared with a standard solution of barbiturates. All solutions for this test must be kept water free. Method: 1 to 2 cc. of blood (or acidulated urine) is pipetted into a small mortar containing sufficient plaster of paris to form a dry mixture. Powder and transfer to a paper extraction shell. Insert into a perforated glass tube connected to a Soxhlet reflux condenser. Add 10 volumes of chloroform to the extraction flask and heat to boiling for half an hour on a water bath. Filter the chloroform extract and test. If the test is negative, concentrate the extract on a water bath and retest. To 1 cc. of the chloroform extract add 0.05 cc. of cobalt acetate solution (1 per cent in absolute methyl alcohol) and 0.3 cc. of isopropylamine solution (5 per cent in absolute methyl alcohol). Compare with standard barbiturate solution containing 0.25 mg. in 1 cc. and treated with 0.05 cc. of the cobalt acetate solution and 0.03 cc. of the isopropylamine solution.

2. The barbiturates are central depressants, and any central depressant such as alcohol, volatile anesthetics, morphine and barbiturates will depress sexual performance while the patient is under their influence. There is no evidence that continued use of the barbiturates will permanently impair sexual function, but it must be remembered that the conditions for which the barbiturates are used may in themselves affect both sexual desire and sexual performance.

VESICAL AND PROSTATIC CARCINOMA

To the Editor:—A man aged 55 has been treated for four years for carcinoma of the prostate. He has had diethylstilbesterol, a bilateral orchiectomy and a prostatic resection. A biopsy at the time of resection confirmed the diagnosis of carcinoma of the prostate. Subsequently the patient had a severe episode of hematuria resulting in a bladder full of blood clots. A suprapubic operation was performed. On removal of the clots neoplastic involvement of the trigone and ureteral orifices as well as the adjacent bladder wall was observed. A biopsy was taken and reported as carcinoma of the bladder. The surgeon doubted the diagnosis of carcinoma of the bladder and thought that the malignant condition was a direct extension from the prostate. It is my understanding that invasion of the bladder wall by carcinoma of the prostate is uncommon. Please discuss this condition and its relative frequency.

Ralph U. Whipple, M.D., Rockville Centre, N. Y.

Answer.—Carcinoma of the prostate occurs in 14 to 25 per cent of men over 50. One half of the cases originate with hypertrophy, and the remainder seem to originate in the posterior lobe independent of hypertrophy or infection. The spread of carcinoma from the prostate is local and/or distant. The distant metastases frequently occur along the vertebral system of veins.

When carcinoma begins in the lateral lobes the spread may occur along the perineural lymphatics and early invade the capsule. In 75 per cent of the cases there have occurred invasion and extension beyond the capsule when the patients first seek medical advice. Local spread may follow the ejaculatory ducts and appear between the seminal vesicles, where it can be palpated in the prostatic notch by rectum. The adjacent bladder wall and surrounding structures are involved early as a result of the contiguity of tissues. However, the bladder wall may remain free until comparatively late in the disease. Bladder invasion can best be determined by cystography and cystoscopy. Ulcerated masses observed near the neck may be indistinguishable from bladder carcinoma except by microscopic sections.

It is sometimes impossible to say whether or not there is a prostatic cancer invading the bladder or a bladder cancer invading the prostate. Cancer of the bladder neck usually invades the prostate early. Cases of this type are far advanced and probably hopeless for cure. Biopsy and microscopic sections are the best aid in the differential diagnosis, provided the metastatic tumors retain their original architecture.

In the case described in the query, if the original biopsy was adenocarcinoma of the prostate the bladder growth might have been a new vesical tumor. However, invasion of the bladder from prostatic carcinoma is not uncommon and is the rule in advanced cases.

ELECTRIC SHOCK AND FETAL DEATH

To the Editor:—What is the amount of electrical shock necessary to cause the death of a six month fetus?

Irvin B. Gardner, M.D., Houston, Texas.

ANSWER.—Reliable information is not available as to the precise amount of electrical shock necessary to cause death of a 6 months fetus.

On theoretical grounds there would appear to be two principal mechanisms by which an appropriate electrical shock might cause death of a fetus: The myometrium might be stimulated to such violent contraction as to cause the uterus to expel its contents or fatal asystole or fibrillation of the fetal heart might be produced.

By either mechanism it would be essential that the electrical contacts were such that the current would pass through the uterus. There are two sources of collateral information from which it can be inferred that fetal death would not be likely to result from either mechanism except by the action of a relatively strong current. One is that uterine muscle is known to lose much of its responsiveness to stimulation during pregnancy. Many stimulants capable of causing contraction of a nongravid uterus become partially or completely ineffective during pregnancy. It is probably also true that the fetal heart is less susceptible to severe disturbance by electrical shock than is the heart of an adult.

Thus, although there is no direct information as to the amount of current required to kill a fetus it can be inferred that in order to attribute fetal death to an electrical shock it should be known (1) that the uterus lay in the pathway of the current and (2) that the current was sufficiently strong to elicit a violent physiologic response in other parts of the maternal organism.

NEGROID CHARACTERISTICS IN INFANT

To the Editor:—An army captain and his wife have started adoption proceedings on a 3 months old infant who is the child of a white woman. The mother will not identify the child's father. The infant now presents a uniform brownish discoloration proximal to the finger nails which is consistent with that seen in an infant of part Negro blood. Otherwise the infant exhibits no unusual characteristics. Can further negroid characteristics be expected to develop in the first twelve months? Is the foregoing sufficient evidence to indicate Negro blood? No history of contact with or injection of heavy metals is available.

Captain, M. C., U. S. Army.

ANSWER.—Discoloration proximal to the finger nails is suggestive of negroid ancestry but in and of itself is not conclusive evidence. When it appears as a result of Negro admixture it generally is accompanied by other suggestive characteristics. The probability that other negroid characteristics will also be present in a child of negroid ancestry is fairly high. A child 3 months old does change considerably within a year and by then could give further evidence of racial admixture. Changes could occur, in particular in mouth, lip, hair and eye features.

ANTAGONISM OF BARBITURATES AND AMPHETAMINE SULFATE

To the Editor:—Is it rational to prescribe together barbiturates and amphetamine sulfate? Would the barbiturate reduce the excitement often caused by amphetamine in depressed patients in the menopause?

M.D., Ohio.

ANSWER.—Amphetamine sulfate and the barbiturates are physiologic antagonists, and the prescribing of the two together is irrational. In depressed states the dosage of amphetamine should be reduced to the minimum necessary to overcome the depression without producing excitement, nervousness or undue wakefulness. Occasionally a barbiturate may be necessary to overcome the effects of slight overdosage of amphetamine, thus permitting the patient to obtain a night's sleep. The barbiturate should be used only when indicated and not prescribed routinely or to be taken at the same time as the amphetamine.

CLOSURE OF PERFORATION OF EAR DRUM

To the Editor:—Is there any method by which an ear drum that has been perforated for two years may be closed? The perforation is marginal and occupies about one half the surface of the drum.

M.D., Pennsylvania.

ANSWER.—There is no method by which a marginal perforation can be closed, since in this type of perforation the epithelium of the canal wall has grown through the marginal gap into the middle ear, leaving no free border to the drum membrane. Central perforations of the drum membrane may sometimes be closed by a technic described by Dr. Ellis Linn of Des Moines, Iowa.

MUSCULAR CRAMPS AND PAIN IN EXTREMITIES IN PARKINSONISM

To the Editor:—A man aged 42 had a severe attack of encephalitis in 1941. At the present time his main complaints are extreme fatigue, headache, insomnia and severe muscular cramps in the feet and legs associated with almost constant severe pain in the lower extremities. Pulsation at the ankles appears to be normal. The patellar reflexes are absent. There are some numbness and loss of sensation below the knees. There is extreme weakness. The appetite is usually good, with some weight gain recently. The mentality is normal. Very few Parkinson symptoms are present. Belladonna used as Bella Bulgara and Rabellon was administered for a long time but has now been discontinued without any apparent changes in symptoms. General complaints narrow down to insomnia. Please discuss treatment.

M.D., Florida.

ANSWER.—From the symptoms described in the query it is suggested that a spinal fluid examination be made. The findings suggest peripheral neuritis or some spinal cord disease. The spinal fluid should be examined for cells, globulin, quantitative total protein, Lange colloidal gold curve and Kahn reactions. If these findings are normal it is suggested that intramuscular injections of liver extract be given two times each week for ten weeks, hypodermic injections of thiamine hydrochloride 150 mg. two times a week for ten weeks and a diet rich in vitamin B.

TRAUMA AND THROMBOPHLEBITIS

To the Editor:—A woman aged 51, with varicose veins of both lower extremities and the abdominal wall, developed thrombophlebitis of several vessels in both upper quadrants of the abdomen just below the costal margins. This followed several weeks' work on a punch press and bench work during which intermittent pressure was exerted on her abdomen but not sufficient to be termed an acute trauma and not severe enough to make her aware of direct trauma. Is this abdominal pressure the cause of the thrombophlebitis?

Emil Franklin, M.D., Milwaukee.

ANSWER.—From the description it would appear that the patient has had an old deep venous thrombosis with obstruction of both iliac veins, since this type of occlusion gives a pattern of collateral veins described in the inquiry. It is known that such collateral veins may thrombose quite readily and that trauma, muscular exercise or infection may precipitate it.

For a discussion of the relationship of trauma and thrombophlebitis one may consult Trauma and Disease, by Brahdy and Kahn (Philadelphia, Lee & Febiger, 1941).

INHERITANCE OF MYOPIA

To the Editor:—What is the possibility of weak eyes in offspring from parents who are both nearsighted, acquired after measles or otherwise? The prospective grandparents have normal eyes, but among the great grandparents there are some nearsighted individuals.

Matt Elsen, M.D., Winnebago, Ill.

ANSWER.—A character acquired as the result of environmental factors has never been known to affect the hereditary materials of reproductive cells in such a way that offspring will have a greater tendency to show the character in question. Accordingly it is the opinion of human geneticists that if the nearsightedness of offspring has been induced by measles or other environmental factors the offspring will have no greater tendency to be nearsighted than would have been true if their parents had not had measles. However, it seems probable that a person who develops nearsightedness due to measles or any other environmental factor has some hereditary disposition in that direction. If this is true, the children might develop nearsightedness under similar circumstances.

There is no question that many cases of nearsightedness are due to hereditary factors. The mode of inheritance apparently differs in different families, but many familial cases seem to follow a simple autosomal dominant mode. For the family referred to in the inquiry it would be impossible to predict results among future offspring.

EXPERIMENTAL PRODUCTION OF MIGRAINE

To the Editor:—In an answer to a question with reference to experimental production of migraine headache, the statement is made (Queries and Minor Notes, The Journal, Oct. 26, 1946, p. 486) that "there is no satisfactory method of experimentally inducing attacks of migraine in persons who are susceptible to them." I would call attention to the observations of Muck (*Münchener med. Wchnschr.* **73**:982, 1926; *Klin. Wchnschr.* **6**:693, 1927), according to which in patients suffering from migraine hyperventilation causes attacks with regularity. I described the probable mechanism of this effect of hyperventilation in migraine in several publications (for example, A New Approach to Dietetic Therapy, Boston, R. G. Badger, 1933, p. 92; A New Aspect of Migraine, *Am. J. Digest. Dis. & Nutrition* **1**:359 [Aug.] 1934). In these contributions I also referred to observations which seem to show that attacks of migraine can be induced in predisposed persons by a diet rich in carbohydrates and liquids.

EPIDEMIC ENCEPHALITIS IN MILITARY PERSONNEL

Isolation of Japanese B Virus on Okinawa in 1945, Serologic Diagnosis, Clinical Manifestations, Epidemiologic Aspects and Use of Mouse Brain Vaccine

ALBERT B. SABIN, M.D.
Cincinnati

A disease clinically similar to the Japanese B type of epidemic encephalitis was known to occur during the late summer months on Okinawa, predominantly among children.[1] However, it was not established that the Japanese B virus was the etiologic agent. On July 8, 1945 several cases of encephalitis were recognized in the native population on Heanza Shima, a small island 2 miles east of Okinawa, by Lieut. L. M. Miller, and on July 10, 1945 Lieut. Comdr. (later Comdr.) Leon Lewis (MC), U.S.N.R., of the Military Government discovered 4 patients with encephalitis in a large civilian hospital on Okinawa.[2] By the end of July, with the aid of the complement fixation test developed by Casals and Palacios[3] a diagnosis of epidemic encephalitis due to virus infection of the Japanese B type was made in several of these early cases by members of the Naval Medical Research Unit 2 who were first on the scene for the investigation of this outbreak.[4] According to Lieut. Comdr. W. Kees (MC), U.S.N.R., who studied the outbreak on the adjacent islands of Heanza and Hamahika, there were 31 cases with onset between July 1 and July 25, 1945 among a native population of 6,547 (an incidence of 4.7 per 1,000) on Heanza and 5 cases on Hamahika during the same period among a population of 1,500 (an incidence of 3.3 per 1,000). This was the total extent of the epidemic on these islands with a case fatality rate of 30.6 per cent. The epidemic on the island of Okinawa continued through August and the early part of September; while 91 cases of encephalitis were found,[2] it was the opinion of Lieut. W. E. Mosher (MC), U.S.N.R., the epidemiologist for the Military Government, that this number may have represented only 15 to 30 per cent of the total, because special conditions precluded discovery of all the cases. Over 80 per cent of the cases were in children 15 years of age or younger, and the case fatality rate was 28.6 per cent.[2]

During the months of July, August and September, 1945, some form of virus infection of the nervous system was suspected in 38 members of the American Military forces. Only 12 of these exhibited severe or moderately severe signs and symptoms of encephalitis and 2 died—1 on August 7 and the other August 17. Most of the others had relatively mild illnesses with transitory nuchal rigidity and reflex changes which, with a few exceptions, were associated with pleocytosis.

ISOLATION OF THE VIRUS

The etiology of the outbreak was established by complement fixation and neutralization tests on the serums of patients in suspected cases and by the isolation of a single strain of virus from a fatal native case.[5] In the first fatal military case, which terminated on the tenth day of illness and exhibited widespread lesions in the brain and cord,[6] a vigorous attempt was made to isolate the virus from the brain and cord. Many mice were inoculated both on Okinawa and in the United States with samples of gray matter taken from both sides of the frontal, parietal and occipital areas of the neopallial cortex, from the cerebellar cortex and from the midbrain, pons, medulla and upper cervical cord, but despite the fact that multiple lesions were present in all these areas, virus was not isolated. The serum of this patient obtained about two days before death had a neutralization index of 32 in the intracerebral test and of 10,000 in the intraperitoneal test against the Japanese B type of encephalitis virus isolated from the civilian patient on Okinawa.[6a] In the second fatal military case, which terminated on the seventh day of illness, the

The work in Okinawa, Japan, and subsequently in the United States of America was performed while Dr Sabin served as a Lieutenant Colonel, Medical Corps, with the Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, United States Army. The investigation was sponsored by the Commission on Neurotropic Virus Diseases, Army Epidemiological Board. Drs. W. McD. Hammon and W. C. Reeves, who came to Okinawa at the end of August 1945, continued with investigations of the outbreak after my departure, and I am greatly indebted to them for many observations.

I wish to express my indebtedness and thanks to Brig Gen. S. Bayne Jones, Deputy Chief, Preventive Medicine Service, Office of the Surgeon General, for this interesting assignment and for all the arrangements which made it possible to carry out this work and to Col. James B Stapleton, Col. Walter B Martin, Major W. G. Downs, Major W. L Forman, Major A S. Benenson and Major (later Lieut Col) Harvey G. Taylor of the Medical Corps, and Capt Carl T. Parsons of the Sanitary Corps, Army of the United States, as well as to Lieut. Comdr. W. Kees, Lieut. Comdr (later Comdr.) Leon Lewis and Lieut Wm. E Mosher of the Medical Corps, United States Naval Reserves, for their help during the course of the work on Okinawa

In the preparation of this paper the attempt has not been made to review the voluminous Japanese literature on Japanese B encephalitis, or to compare the findings herein reported with those claimed by Japanese scientists Most of the work on encephalitis in Japan has been published in the Japanese language, which is a distinct barrier, and furthermore, since 1941 their medical journals have had scant international circulation. For these reasons the bulk of their recent work on this disease has been unavailable for review at the time of writing this paper

[6a] It is believed that the presence of antibodies in the serum of this patient was probably not responsible for the failure to isolate the virus, because during the summer of 1946 R. W. Schlesinger and I isolated Japanese B encephalitis virus from the brain of a soldier who died in Korea on the fifth day of illness, and tests carried out by Capt. David Ginder, M.C., on the serum taken twelve hours before death revealed an intracerebral neutralization index of 10,000 (unpublished data).

brain of the patient was removed by another pathologist and delivered in solution of formaldehyde, precluding any virus studies. The brain was turned over to Lieut. Comdr. (later Comdr.) H. M. Zimmerman [7] of the Naval Medical Research Unit 2. He found widespread pathologic changes compatible with a diagnosis of encephalitis. The serum of this patient taken the day before death failed to neutralize the virus by the intracerebral route (neutralization index of 1) but exhibited definite, though irregular, neutralization by the intraperitoneal route.

Isolation of virus was attempted from the brain tissue of patients in 3 fatal native cases, with only 1 successful result.[7a] The patient from whose brain virus was isolated was a 13 year old girl who died on the fifth day of illness. The necropsy was not performed until ten hours after death, but specimens of tissue taken from the same areas of the brain and cord as those listed previously were immediately used for mouse inoculation. Portions of each piece used for preparation of this suspension were also sent in 50 per cent buffered glycerin [7b] and 50 per cent isotonic solution of sodium chloride to the laboratory of the Naval Medical Research Unit 2 in Guam, but no virus was obtained from the glycerinated material. The mice used for isolation of virus were brought from the United States and kept in screened cans. All 5 mice inoculated with the freshly prepared suspension of material from the human brain and cord exhibited signs of involvement of the central nervous system six or seven days after inoculation (table 1), and on passage of the mouse brain suspension the incubation period was reduced to four days. The bacteria-free agent thus transmitted in series was identified immunologically as a strain of the Japanese B encephalitis virus by both neutralization (table 2) and complement fixation (table 3) tests.[8] The slight cross reaction of the Okinawa virus antigen with St. Louis encephalitis immune serum is in keeping with the known existence of a slight antigenic relationship between the Japanese B, St. Louis and West Nile viruses.[9] Immune serum against the virus of Russian spring-summer tick-borne encephalitis failed to neutralize even the smallest amounts of the Okinawa virus. The Okinawan strain of virus after only a few mouse brain passages proved to have the same degree of pathogenicity for mice (table 4) as the well established Nakayama strain of Japanese B virus after hundreds of mouse passages. While the Okinawa virus does not give rise to clinical signs of infection in intracerebrally inoculated rabbits and guinea pigs (aside from a possible transitory febrile reaction), it produces an antibody response in these animals suggestive of an inapparent infection.

TABLE 1.—*Isolation of Virus from Brain and Cord of Fatal Civilian Case and Passage in Mice*

Passage	Inoculum	Result of Mouse Inoculation *
I	Human brain and cord, 20 per cent suspension; 0.03 cc. intracerebrally, 1 cc. intraperitoneally	6, 6, 7, 7, 7
II	10 per cent mouse brain suspension; 0.03 cc. intracerebrally, 1 cc. intraperitoneally	4, 4, 4, 4, 4
III	1 per cent mouse brain; 0.03 cc. intracerebrally	4, 4, 4, 4

* Numbers in this column refer to days after inoculation when each mouse first exhibited signs of involvement of the central nervous system.

Test for Virus in Lung Tissue.—The patient from whose brain this virus was isolated also exhibited a bronchopneumonia post mortem, a complication not infrequently seen in fatal cases. Several pieces of affected lung tissue obtained from this patient at necropsy and preserved in 50 per cent buffered glycerin and 50 per cent isotonic solution of sodium chloride in the cold were tested for virus by mouse inoculation, but none was isolated.

Tests for Virus in Cerebrospinal Fluid and Blood.—Cerebrospinal fluid was obtained about twelve hours before death from the civilian patient whose brain yielded virus, and was immediately inoculated into 5 mice. Three of the mice remained well; 2 died on the twentieth and twenty-first days after inoculation. Passage of the brain of one of these mice did not yield any virus. In addition to this case, cerebrospinal fluid, obtained from 4 military patients (2 on the fourth day, 1 on the fifth day and 1 on the eighth day of illness, just two days before death) was tested for virus with negative results; the diagnosis of encephalitis due to Japanese B virus was established in these instances by serologic tests. The cerebrospinal fluid obtained from 2 military patients, in whom the diagnosis was not confirmed by serologic tests, on the third and fourth days of illness also failed to yield any virus. The patients' blood was tested in 2 proved military cases on the third and fourth days of illness and in 2 civilian cases on the second day of illness with negative results.

SEROLOGIC DIAGNOSIS IN MILITARY CASES WITH SUSPECTED VIRUS INFECTION OF THE CENTRAL NERVOUS SYSTEM

The ideal goal in establishing by serologic methods that a given infection of the nervous system is caused by a specific virus has been to have a serum taken early enough in the disease to be without any antibodies for the virus and another serum taken at a later stage when such antibodies can be demonstrated unequivocally. At the time of this outbreak there was little or no information on the extent to which this goal may be achieved in patients with Japanese B type of encephalitis. Specimens of serum were obtained from all military patients as soon after onset as they were seen and at subsequent intervals whenever possible. The serums were stored in an ordinary refrigerator for periods of from one to three weeks before they were lyophilized from the frozen state in the laboratories of Naval Medical Research Unit 2 in Guam through the kind cooperation of Capt. (later Commodore) T. M. Rivers (MC), U.S.N.R., and Lieut. H. L. Hodes (MC), U.S.N.R. The lyophilized serums were transported to the United States in the cold and subsequently stored in an ordinary refrigerator until they were tested for both neutralizing and complement fixing antibodies.

An attempt to do complement fixation tests on Okinawa with lyophilized Japanese B virus antigen kindly supplied by Dr. J. Casals of the Rockefeller Institute was unsuccessful because the antigen was anticomplementary in the overnight refrigerator incubation, although it was not anticomplementary after the preliminary incubation in the water bath at 37 C. It was subsequently found that the anticomplementary factor in such reconstituted lyophilized antigens can be removed by angle centrifugation at 3,500 to 5,000 revolutions per minute for one hour. The final results shown in tables 6 and 7, however, were those obtained with freshly prepared mouse brain antigen from the Okinawa strain of virus, because a comparative test showed such an antigen to be more sensitive (table 5). Incidentally, using the Swedish angle centrifuge, the antigen had to be centrifuged at about 3,500 revolutions per minute for at least three hours after repeated freezing and thawing before it was satisfactory for use. The final criterion for a good antigen was that in its presence the complement had to yield the same titer after storage in the refrigerator for eighteen hours as after incubation at 37 C. for one half hour in a water bath and, in each instance, a higher titer than in the control tubes containing isotonic solution of sodium chloride.[9a] The Japanese B and St. Louis types of encephalitis antigens and the western type of equine encephalomyelitis antigen were used undiluted, and repeated titrations indicated that 8 to 16 units of antigen were contained in this dose. The results of each test were checked with either mouse or human immune serum of known titer. The serums were heated at 60 C. for twenty minutes. The neutralization tests were carried out by the intracerebral route with the use of a constant amount of serum against varying amounts of the Okinawa strain of virus, incubating the mixtures at 37 C. for two hours.

[7a] This work was done in association with Lieut. Comdr. L. Thomas and Lieut. J. L. Peck of the Naval Medical Research Unit 2.

[7b] The glycerin was buffered at pH 7.6 with phosphate buffer.

[8] The identity of this same strain of virus subsequently was also confirmed in the laboratories of Naval Medical Research Unit 2 by a complement fixation test.[4]

[9] Casals, J.: Immunological Relationships Among Central Nervous System Viruses, J. Exper. Med. **79:** 341-359, 1944.

The 10 patients with positive serologic tests for Japanese B encephalitis virus and the 2 patients who died are listed in order according to the date of onset in table 6, and the 12 patients in whom the results were entirely negative are similarly listed in table 7. The data in table 6 on serial specimens of serum, available on all but the 2 fatal cases (2 and 8) and case 12, indicate a sufficient change in titer in either the complement-fixing antibody or the neutralizing antibody to permit a specific diagnosis of encephalitis due to Japanese B virus

TABLE 2—*Identification of Okinawa Virus as Japanese B by Intracerebral Neutralization Test with Known Rabbit Immune Serum (Nakayama Strain)*

[9a] During the summer of 1946 the complement fixation test was used extensively in the Tokyo laboratory of the Commission on Virus and Rickettsial Diseases I found that the second requirement in my criteria for a good antigen, namely, that the complement titer in the presence of antigen be higher than in the control tubes containing isotonic solution of sodium chloride, was frequently unobtainable, and yet such antigen could be used satisfactorily.

infection. The data in table 6 furthermore illustrate the following important points:

1. The neutralizing antibody, as determined by the intracerebral test, was equivocally or distinctly positive as early as three to four days after onset (i. e., fourth or fifth day of disease), indicating how difficult it is, by the use of this test, to achieve the desired goal of having an early specimen without antibody followed by a later one in which antibody is definitely present as long as five weeks may be required before the antibody either appears or increases to satisfactory titer (see especially cases 3 and 4).

5. Early in the course of the disease (for as long as three weeks in case 3) the patient's serum may have neutralizing antibody but no complement-fixing antibody (cases 2, 3, 4 and 5). In 1 patient (case 10) only was the reverse true—the serum obtained two days after onset had no neutralizing antibody but fixed complement in a dilution of 1:4, specifically with the Japanese B antigen

12 ‡	Hut	Aug 27	18	100	1:16; (1:32)*	..	0	Fever, nuchal rigidity, drowsiness, bilateral horizontal nystagmus WBC 16 500 CSF 305 cells

These abbreviations, notes and footnotes (* and †) also apply to table 7

Abbreviations Jap B, Japanese encephalitis virus mouse brain antigen; SLF, St Louis encephalitis virus mouse brain antigen; WEE, Western equine encephalitis virus mouse brain antigen; WBC, leukocytes per cubic millimeter of blood, and CSF, cerebrospinal fluid cell count The numbers of cells refer only to white cells

Notes The complement fixation titers represent the original dilutions of serum which gave 2+ or better fixation. 0 means that the 1:2 dilution of serum gave no fixation

Where two titers separated by a semicolon are given, they represent the results of different tests Where two or more figures separated by commas are given for CSF they represent the cerebrospinal fluid cell counts at different times

* *The complement fixation titers in parenthesis were those obtained by the Naval Medical Research Unit 2 investigators,*[4] *and I am indebted to* Lieut John L Peck (MC) U S N R, for forwarding some of these data as well as the serum on patient 12 Although this last serum was sent in the lyophilized state, unrefrigerated, by regular air mail from Guam to Cincinnati, there was only a twofold difference in the complement fixation titers obtained in the two laboratories

† This serum was tested in Dr. W. McD Hammon's laboratory, and I am indebted to him for the result

‡ Patient 12 received two doses of mouse brain vaccine on Aug 11 and 14, 1945, which may be responsible for his serologic response rather than infection with Japanese B virus

2. An approxmately tenfold or greater increase in the intracerebral neutralization index was demonstrable in 5 of the cases (3, 4, 6, 7 and 10) with a sufficient number of convalescent specimens, but it should be noted that this increase may not occur until from three to five weeks after onset, and perhaps even later.

3. Complement-fixing antibody in low titer, i. e, 1:2 to 1:8 the original dilution of the serum, was also found as early as from two to seven days after onset in 6 of 9 patients.

4. An increase in complement-fixing antibody titer occurred in each of the 9 patients on whom serial specimens were available, but again it should be observed that

6. Cross reaction with the St. Louis encephalitis virus antigen in the complement fixation test was observed in only 1 patient (case 1) forty-eight days after onset when the serum had a titer of 1:32 with the Japanese B antigen and 1:4 with the St. Louis virus. Since an earlier serum (seventeen days after onset) from the same patient gave a negative reaction to the St. Louis antigen, it would appear that the low titer of the positive reaction occurring forty-eight days after onset represents a late response to the common antigen possessed by these two viruses[9]

7. It is noteworthy that all patients shown in table 6 had severe or moderately severe clinical manifestations of encephalitis, except case 12. The last mentioned patient was the only one in this group to receive Japanese B encephalitis mouse brain vaccine. He had the first dose on August 11 and the second dose on August 14, seventeen and fourteen days, respectively, before onset. In view of the good complement-fixing titer exhibited by this patient, it is probable that his clinical manifestations were caused by infection with Japanese B encephalitis virus, although this is not certain because only one specimen of serum taken seventeen days after onset was available for test.[9b]

		Patient Vin	0/4	0/3	0/4	0/4	0/3		.	$10^{-2.5-?}$	500,000+?

Note: The intracerebral and intraperitoneal tests were carried out simultaneously, the same serum virus mixtures being used
See footnotes of table 2

A number of questions of practical importance are raised by the serologic observations shown in table 6. Since it has been customary to regard intracerebral neutralization indexes in the range of 10 to 49 (especially in work with the virus of the Western type of equine encephalomyelitis, which gives rise to high titers of antibody) as equivocal, it appeared desirable to determine by the intraperitoneal test the significance of intracerebral indexes of 20 to 40 against Japanese B encephalitis virus observed a few days after onset of clinical manifestations of the disease in man. The results of such a test on the serum obtained three days after onset, from a patient (11 in table 6) with severe encephalitis are shown in table 8 and indicate that the intracerebral neutralization index of 20 was equivalent to an intraperitoneal index of at least 500,000. This means that 0.05 cc. of this patient's serum on the fourth day of the disease was capable of neutralizing at least 500,000 mouse LD_{50} doses[10] of Japanese B encephalitis virus by a peripheral route. This would also suggest (*a*) that one is not likely to isolate Japanese B type of encephalitis virus from the blood of patients even a few days after onset and (*b*) that it is doubtful whether or not the circulating antibody titer can be raised sufficiently to make much difference by the amounts of hyperimmune serum that it may be practical to administer. In regard to the best type of test to use for diagnosis, the data in tables 6 and 7 indicate that there was not a single instance of discrepancy between the final results obtained in a given case by the neutralization and complement fixation tests. The complement fixation test carried out with suitably standardized antigens and with amounts of complement not in excess of 2 units (see table 9), as measured in the presence of the antigens used, is superior to the neutralization test for the practical purpose of determining the type of virus infection in a given case, not only because it is more rapid and does not require any animals but especially because it lends itself more readily to quantitative measurement of the antibody, which is absolutely necessary for the demonstration of a rising titer. Since the neutralizing antibody appears extremely early after onset in human beings, it is obvious that for diagnostic purposes this antibody must also be determined quantitatively. The intraperitoneal test, which is most sensitive, is not practical because mice older than fourteen to fifteen days cannot be used. The method of testing multiple dilutions of serum against a fixed amount of virus does not appear to me to be practical for the encephalitis viruses because unless exceedingly small amounts of virus are used (i. e., five to ten LD_{50} doses) serums with high titers in the undiluted state lose their protective capacity on slight dilution; furthermore, it is rather precarious to attempt to work in the five to ten LD_{50} range because (*a*) the mice may succumb irregularly and (*b*) in attempting to hit this dose one may either overshoot the mark and use fifty or more LD_{50} doses, which is too much virus for a satisfactory test, or undershoot the mark and have too many control mice survive. For this reason I prefer, for routine purposes, to use the intracerebral test with undiluted serum against three tenfold dilutions of virus and to use simultaneous titration of the virus in each test. Thus, if the virus is expected to have a titer of 10^{-8} to $10^{-8.5}$, the final virus dilutions tested with the unknown serums are 10^{-6}, 10^{-7} and 10^{-8}, while the virus titration is carried out with normal, undiluted, heated rabbit serum in final virus dilutions of 10^{-6}, 10^{-7}, 10^{-8} and 10^{-9}; the use of 4 mice per dilution permits the use of a single mouse box (25 by 18 by 14 cm.) for each serum without undesirable overcrowding. The results obtained with many human and other serums have led me to regard an approximately tenfold or greater increase in the neutralization index as a significant rise in antibody when the value for the earliest serum tested is in the range of 10 to 50 or more; however, when the serum obtained at the acute stage of the disease is negative with an index of less than 10, an increase in a later specimen to an index of 20 to 40 is suggestive of a rising titer and an index of 50 or more may be regarded as indicating the definite appearance of antibody in a patient who originally had none demonstrable by the intracerebral test.

[9b] Control studies on healthy vaccinated military personnel carried out during the summer of 1946 indicated that a few persons may develop specific complement fixing titers of this magnitude in response to vaccination Therefore a definite diagnosis of infection with Japanese B virus cannot be made in case 12

See explanatory footnotes (* and †) in table 3.

Among the 12 patients with negative serologic tests presented in table 7, a definite clinical diagnosis of encephalitis is possible only in patient 10, who was so ill during the acute phase of the disease that a fatal outcome was expected; but while he recovered physically his mental status was such that he had to be transferred to the neuropsychiatric service. Although the last specimen available on this patient was obtained only twenty-five days after onset, the tests for Japanese B encephalitis antibody were so unequivocally negative that either this may represent a case of unusually late development of antibody which was missed, or the infection was not caused by the Japanese B type of encephalitis virus. All the other patients either had mild, transitory illnesses or had something atypical in their history, but it was natural to suspect that their disease was possibly caused by Japanese B type of encephalitis virus during the course of an outbreak. Subsequent to my departure from Okinawa, Dr. W. McD. Hammon observed and obtained serums from military patients in 14 additional cases of relatively mild illnesses which were suggestive of some form of virus infection of the nervous system; however, only 1 of the 14 had any demonstrable titer of antibody against the Japanese B type of encephalitis virus (personal communication from Dr. Hammon), and because this 1 had received two doses of vaccine six and four days, respectively, before onset, it is not certain whether his antibody was due to infection or vaccination. It seems to me especially noteworthy that in this group of cases it was not possible to prove infection by the Japanese B encephalitis virus in patients who exhibited only nuchal and spinal rigidity, transitory reflex changes and pleocytosis as the only manifestations indicative of involvement of the nervous system—the syndrome ordinarily described as aseptic or lymphocytic meningitis, and, when it is seen during the course of a poliomyelitis epidemic, as nonparalytic poliomyelitis. Although there is good evidence, based on isolation of virus from the stools, that such a syndrome can actually represent nonparalytic poliomyelitis, there was no evidence that during this outbreak it represented a mild form of encephalitis due to Japanese B virus. However, in patients who exhibited this syndrome plus a certain amount of drowsiness, lethargy and mental confusion positive serologic evidence for infection with the Japanese encephalitis virus was obtained.

The infections of the 4 patients (1, 2, 3 and 11) exhibiting severe pain along the course of the sciatic nerves and weakness or actual paralysis of the lower extremities associated with pleocytosis were considered clinically as possible "radicular types of encephalitis" (a textbook syndrome) but may actually have been instances of poliomyelitis. Poliomyelitis perhaps might also have been the more correct diagnosis in case 7, despite the diplopia and bilateral positive Oppenheim signs, for this patient as well as 1, 2, 3 and 11, just mentioned, at no time exhibited any lethargy or mental confusion.

---

[10] Mouse LD_{50} doses: LD_{50} is that dose having a lethal effect on 50 per cent of animals used in experiments.

CLINICAL MANIFESTATIONS IN SEROLOGICALLY POSITIVE MILITARY CASES

The adjective "lethargica" commonly reserved for von Economo's (type A) encephalitis is most applicable to the disease as it was seen in the American military patients in whom a positive diagnosis of encephalitis due to Japanese B virus was ultimately established by serologic methods. Drowsiness, lethargy, mental confusion and disorientation, and semicoma or complete coma in the more severe cases, occurring in association with high fever, nuchal and spinal rigidity, leukocytosis and pleocytosis constituted the most important manifestations for diagnostic purposes. The onset was usually sudden with fever and extremely severe headache, although the mental confusion and lethargy and even the stiffness of the neck and spine (the latter easily demonstrated by the kiss-the-knee test) frequently did not appear until several days later. Actual paralysis was seen only once in this group of patients, and that in a case with early fatal termination. True convulsions were also seen only in the 2 fatal cases. Dissociated eye movements which were not infrequently seen in the native children with the disease[2] were observed in only 1 patient, again in a case with a fatal termination. The pupils, however, were usually contracted and reacted poorly to light. Diplopia did not occur in this group.

A milky, sticky exudate was often seen about the eyes. Athetosis, incoordination and tremor of the hands were not uncommon, and difficulty in writing could be easily demonstrated. Difficulties in speech ranged from slurring to complete aphasia. The reflexes were variable. The abdominal reflexes were usually absent, while the tendon reflexes were most often exaggerated, although occasionally they might become diminished or disappear. Positive great toe reflexes were uncommon.

The fever was high and lasted for from seven to eleven days except in 1 patient in whom a bronchopneumonia also developed. The temperature and pulse curves are illustrated in the charts of 4 patients (charts 1 to 4). The remittent type of temperature curve may perhaps be due to the administration of acetylsalicylic acid, but that is not certain. A relative bradycardia was invariably present during the febrile phase, and a pulse rate of 50 to 60 was common after defervescence. A leukocytosis in the range of 10,000 to 25,000 with a definite increase in the number of mature and immature neutrophils was the rule in these patients and was also found regularly in the native cases by Lieut. John W. Norcross (MC), U.S.N.R.[2] The cerebrospinal fluid was clear, under normal or slightly increased pressure, and pleocytosis, ranging from 22 to 660 white cells per cubic millimeter in the first specimen examined was present in all patients of this group. The cells were predominantly mononuclear, although in 1 acutely ill patient (11 in table 6) most of the 400 cells seen on the third day of the disease were reported as polymorphonuclear. The protein concentration was normal or slightly increased early in the disease, while during convalescence a 3 or 4 plus Pandy reaction was not uncommon. Pellicle formation was observed in at least 1 patient (5 in table 6) on the fifth day of the disease.

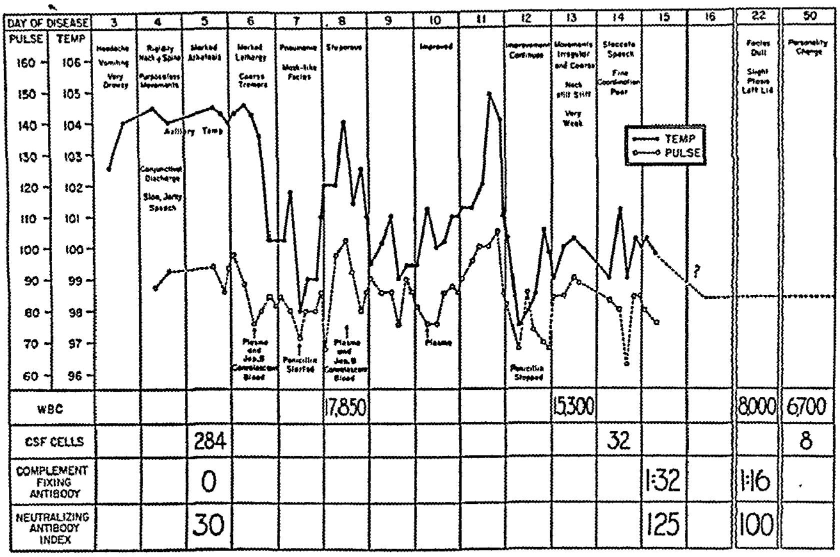

Chart 1.—Japanese B encephalitis in American soldier, M. O. T., aged 29, on Okinawa in 1945.

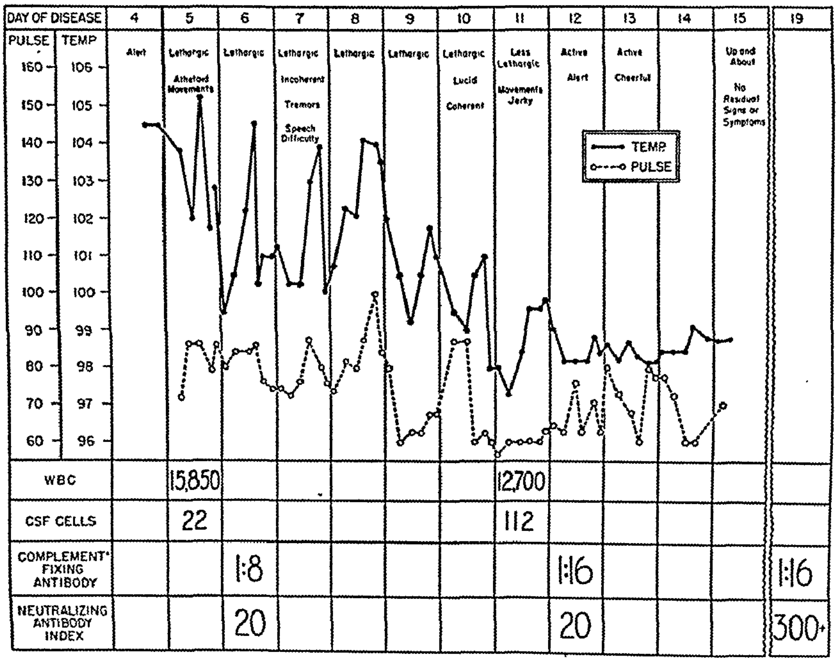

Chart 2.—Japanese B encephalitis in American soldier, R. C. W., aged 23, on Okinawa in 1945.

Convalescence was slow, and lethargy, incoordination, tremors and "nervousness" usually persisted for weeks after defervescence. The condition of at least 1 patient (5 in table 6) was still rated as poor seven weeks after onset, with masklike facies, somnolence, hyperirritability and distinct personality change manifested by stoicism, perverse obstinacy, moroseness, disinclination to talk and urination on the floor of the ward. I have had an opportunity to see some of these patients for only short periods during the acute phase of the infection, and I am indebted to Major Wiley L. Forman, Major Arthur H. Rosenblum and Capt. Charles P. C. Logsdon of the Army Medical Corps and to Lieut. Comdr. W. Kees (MC), U.S.N.R., for the clinical observations and notes on these patients which they were good enough to supply.

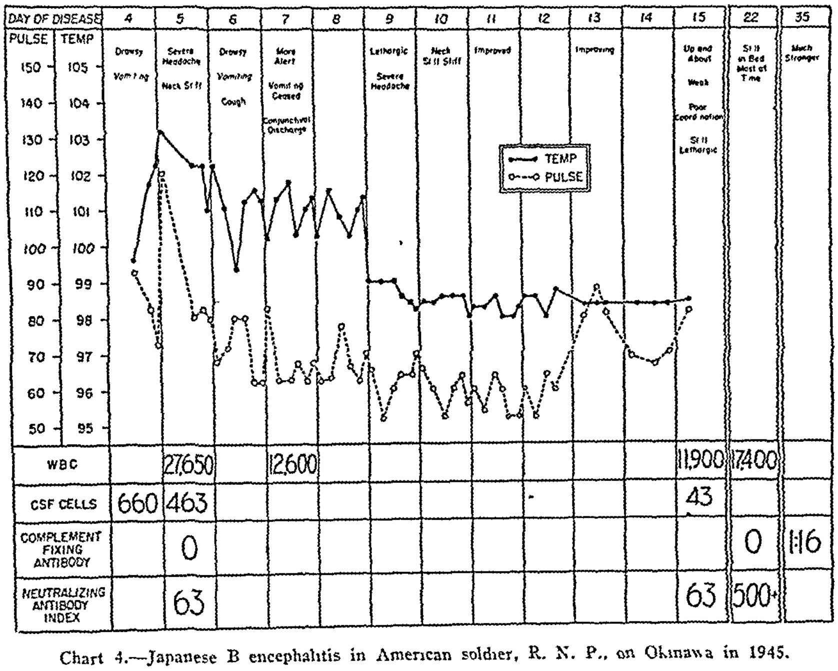

Chart 4.—Japanese B encephalitis in American soldier, R. N. P., on Okinawa in 1945.

EPIDEMIOLOGIC ASPECTS

Endemicity of Encephalitis on Okinawa.—The story related by native physicians suggested that "summer" encephalitis was endemic on the island, occurring yearly with an incidence of usually about 5 infections per 10,000 population and on a few occasions 17 per 10,000, predominantly in the younger age groups. To check on this hypothesis, blood was collected from 60 natives without history of encephalitis. The ages represented ranged from 1 (Okinawan 2, because they are regarded as 1 year old at birth) to 61. The results of intracerebral neutralization tests, using the Okinawa strain of Japanese encephalitis virus, on 57 of these serums shown in table 10 indicate an increasing incidence of antibodies with age. The presence of antibodies in 90 per cent of the 30 persons who were 20 years of age and older and in 55 per cent of 11 persons in the 10 to 19 year age group not only indicates how widespread infection with this virus has been on the island but also explains why, in recent years at least, the clinically manifest disease has been seen predominantly in children. The complete negative results in the 16 children of the 1 to 9 year age group are either fortuitous (Lieut. J. L. Peck informed me that a few positive results were obtained in this age group in similar tests carried out in the laboratory of Naval Medical Research Unit 2) or an indication that the incidence of infection has been lower in recent years. It was of interest to determine to what extent serums exhibiting low, intermediate and high neutralization indexes may also contain complement-fixing antibodies, and the results of such tests on the serums of 12 natives, 10 to 57 years of age, without history of encephalitis, are shown in table 11. Of the 10 serums which were *not anticomplementary and did not cross with the control Western type equine encephalomyelitis antigen*, only 1 gave significant fixation in a dilution of 1 : 8. The most probable explanation for this observation, in view of the data on recent convalescents shown in table 6, is that the complement-fixing antibody for Japanese B type of encephalitis virus antigen disappears at a certain, as yet unknown, period after infection (at least in most instances), while the neutralizing antibody persists. The presence of a high titer of complement-fixing antibody may thus be indicative of recent infection. This fact might be utilized as an epidemiologic tool to determine recent infection rates in certain areas, although the interpretation of the data would hinge on how long the complement-fixing antibody persists.

Vertebrate Hosts Other than Man.—The work of Hammon and his associates,[10a] as well as the isolation in the last few years first of St. Louis encephalitis virus from mites, Dermanyssus gallinae, taken from chickens possessing neutralizing antibodies against this virus,[11] and then of Western type equine encephalomyelitis virus[12] from the same species of mites taken from chickens during an outbreak of the disease in Texas, followed by the demonstration that this type of mite may serve as a true reservoir of the virus by virtue of transovarian passage from one generation of mites to another,[13] made it desirable to determine what vertebrate hosts are infected by the Japanese B virus on Okinawa, and especially whether or not chickens were involved. Although the chicken population on Okinawa and adjacent islands had been greatly reduced by the time the outbreak of encephalitis appeared, a certain number of them could always be found in any native village. The other domestic animals were horses, goats, pigs and, infrequently, a cow, which shared the same living quarters with the human beings. I caught only a fleeting glance at two dogs and a single cat during my entire stay on Okinawa; rats and shrews were plentiful. The blood of 15 horses, 10 goats, 1 cow and 12 chickens from either Heanza or Okinawa was tested for neutralizing antibodies against the Okinawa strain of Japanese B type encephalitis virus. The results shown in table 12 indicate that all 15 Heanza or Okinawa horses (but none of 10 American horses tested simultaneously), the 1 Heanza cow and 3 of the 10 Okinawa goats possessed good neutralizing antibodies, while none were found in any of the 12 Heanza or Okinawa chickens taken from areas where multiple human cases of encephalitis had occurred. Furthermore, either few or no mites could be found on these and other chickens in the encephalitis zones. Another group of Okinawa horses tested by Hodes, Thomas and Peck[14] were also found to contain complement-fixing antibodies for the Japanese B virus. The absence of antibodies in the available chickens and the great scarcity of other birds on Okinawa make one wonder whether some mammalian host such as the horse, goat or cow, or the rats and shrews which unfortunately (for lack of live traps) were not tested, may not play the same role for Japanese B encephalitis on Okinawa as has been suggested for the chicken in the case of St. Louis type encephalitis and Western type equine encephalomyelitis in the United States.[10a] It is noteworthy, however, that Hammon and Reeves[10a] recently reported outbreaks of the two last mentioned diseases in Texas and Nebraska in which chickens could not be implicated as the intermediate hosts from which the mosquitoes derive their initial infection and suggested that the vertebrate hosts, and possibly the invertebrate vectors, may vary from one area to another. Mites or related ectoparasites were not found on the Okinawan horses, goats or pigs by Capt Carl T. Parsons, Sanitary Corps, who was the entomologic associate in this work. He did find a large number of mites on the single available Heanza dove, but inoculation of mice with 130 of these mites yielded no virus

Insect Vectors.—Both Japanese[16] and Russian[17] investigators have reported the isolation of Japanese B encephalitis virus from Culex tritaeniorhynchus and Culex pipiens var. pallens mosquitoes caught in nature. These mosquitoes as well as Aedes togoi, Aedes albopictus, Aedes japonicus[18] and Culex quinquefasciatus,

Culex tarsalis, Aedes dorsalis, Aedes nigromaculis, Culiseta incidens and Culiseta inornata[19] have been demonstrated experimentally to be potential vectors. C. pipiens was not found on Okinawa and C. tritaeniorhynchus was practically absent during late July and August in many districts where cases of encephalitis continued to appear. C. quinquefasciatus was present in abundance for several months before the outbreak and continued to be the mosquito most readily found in homes during August. For every hundred C. quinquefasciatus that Captain Parsons caught in homes he found only two or three Armigeres subalbatus. A few larvae of A. togoi were discovered, but adult mosquitoes could not be found. A. albopictus were not found by Captain Parsons in the encephalitis zone he investigated during August, although this mosquito occurred in varying numbers in other parts of the island. Mosquitoes of the species Anopheles hyrcanus sinensis, although not collected because they are only rarely found in houses and their resting place is still unknown on Okinawa, were not readily controlled by the spraying of DDT (4,4′-dichlorodiphenyltrichloroethane) from airplanes in the mountainous northern portions of the island where many rice paddies, located in narrow precipitous valleys, were inaccessible. C. quinquefasciatus was regarded as the most probable vector, and extracts of a number of pools, which consisted of about 100 of these mosquitoes, were inoculated into mice to test for virus. Satisfactory tests on 3 such pools did not yield any virus, but this is not enough to indicate that the species was not a vector. However, if it had been a vector on Okinawa one would have expected to find evidence of infection in chickens,[20] which are known to be bitten by this mosquito in the United States,[21] and yet the chickens, unlike the horses, goats and cow, were without neutralizing antibodies for the virus. One must consider the possibility, therefore, that some other mosquito biting the larger domestic animals and human beings by preference might have been the vector on Okinawa.

What I looked for, and did not find, was direct evidence for the working hypothesis that a mitelike insect, constituting the real reservoir of the virus through winter and summer and from generation to generation, gives rise to virusemia in one or another of the domestic animals, with subsequent dissemination to human beings and other hosts by the mosquitoes which breed in large numbers during the hot spell following the rainy season. This may still be the true epidemiologic cycle despite the fact that neither the "mite" nor the mosquito which might have carried this virus has as yet been found on Okinawa.

Influence of Proximity to Native Population and Domestic Animals on the Occurrence of Encephalitis Among Military Personnel.—Not a single case of encephalitis occurred among the two thirds or more of the total forces which occupied the southern portion of Okinawa, from which practically the entire native population and their domestic animals had been removed for military reasons. It is also noteworthy that all the proved cases of Japanese B encephalitis in military personnel occurred in the extreme northern portion (Hentona, Taira and Motobu peninsula districts). According to Major W. G. Downs, M. C., in charge of preventive medicine for the Island Command, this was also the area in which the control of mosquitoes breeding in rice paddies was much less complete because of the difficult terrain, and in which an outbreak of malaria due to Plasmodium vivax affecting 6,000 to 8,000 natives and several hundred troops occurred at the same time as the epidemic encephalitis.

USE OF MOUSE BRAIN VACCINE

The Japanese B encephalitis mouse brain vaccine developed in 1942 in this country[22] was originally a lyophilized preparation, in which the solution of formaldehyde was neutralized by sodium bisulfite. Because preliminary trials at the laboratories of Sharp & Dohme, Inc., indicated that good lyophilization could not be obtained by the large scale production methods used in 1943, the vaccine that was finally prepared by different biological houses for the Armed Forces was a preparation in liquid form, consisting of a 10 per cent suspension of mouse brain in isotonic solution of sodium chloride, in which the virus had become inactivated by 0.2 per cent solution of formaldehyde in the cold. The minimal requirements for the protective potency of the vaccine were that at least 0.01 cc. of it should constitute a minimal immunogenic dose as determined by an intraperitoneal method of assay in 18 to 20 Gm. mice.[23] The vaccine administered in two doses three days apart produces immunity in mice within one week after the first dose at a time when no antibodies are demonstrable in the blood by the intracerebral neutralization test. Since the vaccine was to be used in the face of an epidemic, two doses of 2 cc. each given three days apart were decided on for general use. Preliminary tests on 35 persons receiving this amount of a vaccine with a minimal immunogenic dose of 0.0054 cc. indicated that in 18 of 25 (72 per cent) persons 35 years of age or younger and in 2 of 10 (20 per cent) 36 years of age or older antibody demonstrable by the intracerebral neutralization test had developed two weeks after the first dose.[23] Since vaccinated mice show good resistance to peripheral inoculation of virus without demonstrable antibody by the intracerebral test, it was believed that the selected dosage might be sufficient to impart the needed resistance during the short epidemic period of encephalitis due to the Japanese B type of virus. It must be granted that this dosage may be inadequate, but it was desirable to avoid administration of large amounts of this vaccine. The commercially prepared vaccines assayed 0.003 cc. to 0.01 cc. for the minimal immunogenic dose and were transported to Okinawa in insulated boxes containing ordinary ice.

Smorodintseff[24] reported that a similarly prepared vaccine has proved effective against the Russian autumn encephalitis (Japanese B) in that among 8,030 unvaccinated persons there were 59 cases of encephalitis with 18 deaths while among 10,485 vaccinated persons there were only 2 mild cases and no deaths. The military situation and other conditions obtaining on Okinawa in July and August 1945 did not permit any controlled study of the protective value of the vaccine. It was considered, along with mosquito control, among the measures that may reasonably be used in the attempt to protect exposed troops against a disease with a reported average case fatality rate of 60 per cent. Approximately 800 to 1,000 military government per-

TABLE 13.—*Summary and Analysis of Neurologic Reactions Reported for 55,403 Persons After Vaccination with Japanese B Encephalitis Mouse Brain Vaccine on Okinawa (1945)*

Case	Interval Between Onset of Symptoms and Vaccination	Signs and Symptoms	Outcome	Diagnosis	Relation to Vaccination
1. C. C.	On day of 1st dose	Pain in back and thoracic region; next day the left trapezius, serratus and sternocleidomastoid muscles were weak	Later discounted as "reaction" by reporting officer	?	..
2. C.	5 days after 2d dose (8 days after 1st dose)	Drowsy	Drowsy in hospital for 2 or 3 days; recovery without noteworthy events	None	..
3. J. B. G.	5 days after 2d dose 8 days after 1st dose	Headache, dizziness, blurring of vision; complained of stiff neck but no nuchal rigidity. "Moderate weakness of quadriceps muscle." CSF 2 cells	6 days after onset "headache gone; muscular weakness gone"	?	?
4. J. W. J.	4 days after 1st dose 1 day after 2d dose	Numbness of left forearm and wrist drop 2 days later; temp. and CSF normal; history of chronic alcoholism	Function in forearm returning 9 days after onset	Peripheral neuritis involving left radial nerve; "Sat. night paralysis"	..
5. H. R. K.	2 days after 1st dose (2d dose given 4 days after 1st)	Generalized aches, pains and weakness growing progressively worse at night; examination 9 days after onset revealed apparent weakness in all muscle groups; hamstrings tight and painful with hyperesthesia on pressure; kneo jerks, ankle jerks and biceps reflex absent; no fever; CSF 2 cells, globulin negative but protein recorded as 178.2 mg. per 100 cc.	No information available	Peripheral neuritis ?; infectious polyneuritis ?	Very questionable because symptoms appeared 2 days after vaccine
6. C. A. T.	10 days after 1st dose 6 days after 2d dose	Numbness and weakness of arms and legs; no pleocytosis, 3 days after onset; 2 weeks after onset, motor weakness of arms and legs but no reflex changes	4 weeks after onset evacuated with note: "Extreme muscular weakness, fatigue, altered superficial and deep reflexes." No other information available	Polyneuritis ?	Possible
7. G. B. L.	15 days after 1st dose (There is some question as to whether 2d dose was given 10 days after 1st)	"Headache, stiff neck and malaise sudden onset of flaccid paralysis of both lower extremities excluding the feet, and marked weakness of the forearms and fingers; possible weakness of right lateral rectus muscle; absent kneo jerks and ankle jerks; temperature never over 99.6 F.; CSF 3 cells"	Much improved 10 days after onset; paralysis receded with return of leg reflexes; walking 19 days after onset with only slight weakness of both quadriceps	Infectious polyneuritis ?	Possible
8. E. J.P.	7 days after 1st dose 3 days after 2d dose	Gradual onset of weakness in arms and legs; at peak of weakness could not raise hands to wash face and was able to rise from a chair only by pulling himself up with hands; sensation undisturbed and all reflexes reported normal; reports on muscle atrophy incongruous; CSF, 180 mg. protein per 100 cc.; afebrile	Improvement began 10 days after onset. Examination by Dr. C. D. Aring 6 months after onset revealed nomal gait, no muscle atrophy or weakness and no abnomalities beyond disturbed emotional state.	Infectious polyneuritis ?	Possible

sonnel operating in areas where most of the civilian cases were occurring were vaccinated between July 15 and 20, i. e., about seven to ten days after the first cases had been reported. It is perhaps noteworthy that the single case of encephalitis (onset August 8) which occurred among military government personnel was in a hospital corps man (case 7, table 6) who was not vaccinated. When the number of civilian cases continued to increase and a certain number of probable and suspected cases of encephalitis had been diagnosed in military personnel, it was decided to vaccinate those who were in close proximity to areas where civilian cases were occurring. This decision was reached at a time when the future course of the outbreak could not be predicted and was largely based on the consideration that it was not wise to gamble on the chance that relatively few cases would occur or to rely entirely on mosquito control measures.

Enough vaccine was distributed to provide two doses of 2 cc. each for about 77,000 persons, and 60,000 to 70,000 were probably vaccinated. Through the efforts of Major W. G. Downs, M. C., reports were received on 53,139 persons who received the two doses and 2,274 who had only one dose, and the following information originates in part from his summary. The 61 local reactions which were reported consisted mainly of pain and swelling at the inoculated site with, in some instances, enlargement of the axillary lymph nodes and included 5 cases of infections requiring incision and drainage. The latter all came from two small units and may have represented a break in aseptic technic. There was also a good deal of variation either in what was considered a local reaction or in recording it, for one Army division with 12,380 men inoculated with two doses reported only 1 local reaction, while a Marine division with 18,991 men similarly inoculated reported 35 local reactions. Systemic reactions characterized generally by headache, fever, malaise and occasionally nausea and vomiting occurring within twenty-four to forty-eight hours after inoculation were reported in only 19 persons, but it is probable that there were more. However, it was apparent that systemic reactions were infrequent and certainly much less common than similar reactions following the administration of typhoid vaccine. Nineteen allergic reactions characterized by urticaria sometimes with angioneurotic edema and often with moderate difficulty in breathing, all with good response to epinephrine, were reported. Comdr. B. R. Reinertsen (MC), U.S.N.R., kindly supplied the following note on 1 such case: "Fifteen minutes after injection, the patient noted nausea, tightness of the throat, mild dyspnea and tingling of the fingers. Examination revealed a minimal amount of cyanosis. Twenty minutes after the injection of a solution of 5 minims (0.3 cc.) of epinephrine subcutaneously, there was relief of the dyspnea, sensation of tightness of the throat and tingling. Ten minutes later there developed a generalized urticarial rash with discrete large wheals. Again the patient was treated with a solution of 3 minims (0.2 cc.) of epinephrine subcutaneously. Urticaria subsided in approximately one hour, and there were no symptoms remaining." Since mouse brain represented a new antigen for American military personnal one must consider the possibility that some, if not all, of these allergic reactions may be instances of sensitization to solution of formaldehyde resulting from previous inoculations with other vaccines preserved in this drug; 1 man in this group himself advanced the history of sensitivity to formaldehyde. Horsfall[25] has demonstrated that formalized protein can induce antibodies and hypersensitiveness not only to the homologous preparation but also to heterologous formalized proteins.

A summary and analysis of the 8 neurologic reactions which were reported are presented in table 13, and the following points are especially worthy of note:

1. There was not a single instance suggestive of demyelinating encephalopathy.
2. In 3 of the 8 cases (1, 2 and 3 in table 13) the manifestations were so slight that no diagnosis could be ventured.
3. In the 5 remaining cases, in which "neuritis" of one form or another was the most probable diagnosis, case 4 occurred in a chronic alcoholic addict and was of the typical "Saturday night paralysis" radial palsy variety, and case 5 had its onset two days after the first dose, rendering its relationship to vaccination highly improbable.
4. Only 3 significant neurologic reactions may possibly be related to vaccination; in the 2 more severe cases improvement began ten days after onset and almost complete recovery is reported.
5. Before the vaccination program was begun on Okinawa the diagnosis of neuritis was made in 3 military patients (cases 1, 2 and 3 in table 7) who were considered as possibly representing "radicular types of Japanese B encephalitis," but this diagnosis was not confirmed by serologic tests.
6. Various types of neuritis have previously been reported following the administration of foreign protein serums, typhoid vaccine and the like, although it is doubtful that the etiologic relationship of these inoculations is unequivocal.

Conclusions cannot be drawn regarding the protective value of the vaccine from the data obtained on Okinawa. For various reasons the general vaccination program did not get under way until the second week in August, and all the indications are that the epidemic was practically over by the last week of August—the last serologically proved military case had its onset August 21. It was pointed out earlier, in the remarks on the data in table 7, that in a considerable number of patients with varying signs suggestive of involvement of the nervous system there was no serologic evidence of infection with the Japanese B type encephalitis virus (the tests were also negative for St. Louis and Western equine types). Data obtained by Dr. Hammon, who remained in Okinawa after I left, showed that cases of this type continued to occur in September in both vaccinated and unvaccinated personnel. There were 2 vaccinated patients in this group who had complement-fixing antibodies as well as neutralizing antibodies (patient 12 in table 6 and patient Bro. tested by Dr. Hammon), who might represent infection with the Japanese B virus, although it is not improbable that their antibodies might have resulted from vaccination; 1 (Bro.) had his first symptoms six days after the first dose and four days after the second dose, while the other's symptoms began sixteen days after the first and thirteen days after the second dose of vaccine.

SUMMARY

1. During an outbreak of encephalitis in the native population on Okinawa during July, August and the early part of September 1945, there were 38 cases of suspected virus infection of the nervous system among American military personnel. A definite clinical diagnosis of encephalitis was probably justified in only 12 of these cases, and 2 of these patients died.
2. A virus which was identified as that causing the Japanese B type of encephalitis was isolated from the brain of a native who died on the fifth day of the disease. No virus could be obtained from the brain of the 1 military patient who died on the tenth day, despite the fact that multiple lesions were present in the areas from which material was taken for mouse inoculation. No virus was obtained from the lung tissue, cerebrospinal fluid or blood of patients with specific evidence of infection.
3. Serologic tests on serums obtained at different intervals after the onset of infection revealed that appreciable amounts of neutralizing antibody were present as early as three days after the onset of symptoms and that, as a rule, it was not possible, therefore, to establish a specific diagnosis on the basis of the absence of this antibody in specimens taken in the acute stage and its appearance during convalescence. It was necessary to demonstrate a definite increase in the amount of neutralizing antibody by a quantitative method.
4. It was established that 0.05 cc. of a patient's serum having an intracerebral neutralization index of 20 three days after onset was capable of neutralizing at least 500,000 mouse LD_{50} doses of Japanese B encephalitis virus by the intraperitoneal route.
5. With properly standardized antigens, the complement fixation test was found to be the method of choice for practical purposes. The necessary increase in titer or even its first appearance may be delayed for as long as five weeks after onset.
6. Neutralizing antibody without complement-fixing antibody was found early in the disease (in 1 instance for as long as three weeks after onset) and also in Okinawan natives without a history of encephalitis who had had their infection some time in the past.
7. With the aid of both the neutralization and complement fixation tests, a specific serologic diagnosis of encephalitis due to Japanese B type of virus was established only in 9 American military cases in addition to the 2 fatal cases.
8. In the patients in whom tests gave serological proof of Japanese B virus infection, drowsiness, lethargy, mental confusion and disorientation, semicoma or complete coma in the more severe cases, occurring in association with high temperatures, nuchal and spinal rigidity, leukocytosis and pleocytosis were the chief clinical manifestations of importance for diagnostic purposes.
9. The history of endemicity of the disease on Okinawa advanced by native physicians found support in the demonstration of neutralizing antibodies in 90 per cent of Okinawan natives without a history of encephalitis who were 20 years of age or older (group of 30), in 55 per cent of 11 persons in the 10 to 19 year age group and in none of 16 persons in the 1 to 9 year age group.
10. Neutralizing antibodies were also demonstrated in all 15 Heanza or Okinawa horses tested (not in any of 10 American horses tested for control), in at least

[25] Horsfall, F. L., Jr.: Formaldehyde and Serum Proteins: Their Immunologic Characteristics, J. Immunol. **27**: 553-567, 1934; Formaldehyde Hypersensitiveness: Experimental Study, J. Immunol. **27**: 569-581, 1934

3 of 10 Okinawa goats, in 1 Heanza cow but in none of 12 Heanza or Okinawa chickens This may indicate that domestic fowls probably do not play the same role in the epidemiology of encephalitis due to Japanese B virus on Okinawa that they are believed to play in some but not all, areas of the United States where the St Louis type encephalitis and the Western type equine encephalitis have occurred. The fact that the larger domestic animals such as the horse, goat and cow are attacked would point to mosquitoes, which bite these animals and human beings by preference, as the probable vectors

11 Although Culex quinquefasciatus was the predominant mosquito on Okinawa during the course of the outbreak, evidence was not found to indicate that it was the vector The negative, limited tests for virus as well as the absence of antibodies in chickens may indeed be regarded as evidence against it

12 No cases of encephalitis occurred among the more than two thirds of the total armed forces quartered in the southern part of the island from which almost the entire native population and their domestic animals had been removed The serologically proved military cases all occurred in the extreme northern portion of the island (Hentona, Taira and Motobu peninsula districts) where the control of mosquitoes breeding in rice paddies was incomplete because the difficult mountainous terrain made them inaccessible to DDT spray from airplanes and other means of dispersion, it was in these same areas that an outbreak of malaria due to Plasmodium vivax in 6,000 to 8,000 natives and several hundred troops occurred at the same time as the encephalitis

13 Japanese B encephalitis mouse brain vaccine was administered to 60,000 to 70 000 of the military personnel stationed in the northern portion of the island in proximity to civilian foci of infection Special conditions obtaining on Okinawa did not permit any conclusions in regard to the protective value of the vaccine or the adequacy of the dosage used There was not a single instance suggestive of demyelinating encephalopathy among the 53,139 persons receiving the two doses and the 2,274 who received only one dose of the vaccine, on whom reports were obtained Three cases of one form or another of "neuritis" reported in this group may or may not have been related to the vaccination, since cases of "neuritis" were also seen in persons who did not receive the mouse brain vaccine The report of 19 instances of allergic reactions in this vaccinated group suggests the possibility that in some, if not all of these, sensitization to solution of formaldehyde might have been a factor

ADDENDUM

Approximately 250 000 additional persons received two or three doses of mouse brain vaccine during the summer of 1946 Again there was not a single case suggestive of demyelinating encephalopathy At least 3 cases of a syndrome suggestive of infectious polyneuritis and in no way different from that occurring among unvaccinated personnel in the Far East were seen One of these patients died, and the only significant pathologic changes were found in the nerve roots and were of the same type seen in fatal cases of the Guillain-Barré infectious polyneuritis syndrome In this patient, as well as in several others who died of typical poliomyelitis subsequent to vaccination, demyelinating lesions were not found in the central nervous system

DEVELOPMENT AND USE OF BAL

A Review, with Particular Reference to Arsenical Dermatitis

MARION B SULZBERGER, M D
and
RUDOLF L BAER, M D
New York

Basing his opinion on previous studies, in particular those of A Heffter and collaborators in 1903 and 1908,[1] P Ehrlich[2] in 1909 stated his idea that the toxic action of arsenic is due to its attack on sulfhydryl (SH) compounds or "arsenoreceptors." These compounds were recognized as essential to biologic oxidation and reduction processes Many other investigators have advanced the thesis that metallic compounds and certain other poisons combine with the thiol groups of tissue enzymes or of members of oxidation and reduction systems, such as glutathione and cysteine, and thus inactivate these constituents necessary to life and function Long before World War II the concept was generally held that "detoxification" of arsenic and of certain other metallic and even nonmetallic compounds may be accomplished by administration of chemicals containing thiol groups One of the early fundamental studies of this effect was that of C Voegtlin, H A Dyer and C S Leonard,[3] who in 1923 demonstrated the detoxifying effects of sulfhydryl compounds (glutathione and cysteine) on arsenic And at about the same time Hopkins and Dixon[4] and Peters and Walker[5] found that certain arsenicals abolished the fixed —SH (sulfhydryl) in washed muscle tissue and in the "active" layer of the skin

THE DEVELOPMENT OF BAL (DIMERCAPROL) IN ENGLAND

However, it remained for the English scientists R A Peters, L A Stocken and R H S Thompson[6] to advance the theory that agents which "tie up" the —SH groups of the tissues will interfere with the activity of the pyruvate oxidase system, which is dependent on the —SH groups for its activity They then went on to show that dithiol compounds would tend to have greater affinity for certain arsenicals and would form relatively nontoxic and more stable compounds with these arsenicals than would either monothiols or "dithiol" proteins in the tissues They observed a close relationship between the arsenic content of a lewisite-kerateine compound and the thiol content of the kerateine One of their most significant findings was that when aqueous solution of kerateine was treated with lewisite, 75 per cent of the arsenic found in the lewisite compound was in combination with two thiol groups

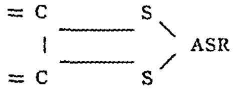
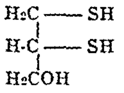
[6] Peters, R A, Stocken, L A, and Thompson, R H S British Anti Lewisite (BAL), Nature, London **156**·616, 1945

Their idea was to compete for the arsenic with the dithiol-containing proteins in the tissues by offering simple synthetic dithiol compounds which might form *relatively nontoxic and stable ring compounds such as*



The researches of Peters, Stocken and Thompson led to the use of 2,3-dimercaptopropanol



$$\begin{array}{l} H_2C\text{—}SH \\ \;| \\ H\text{-}C\text{—}SH \\ \;| \\ H_2COH \end{array}$$

as a detoxifying agent against the arsenicals of chemical warfare. This agent could not only prevent the toxic action but reverse it, provided that "the toxicity had not been too long established." As this 2,3-dimercaptopropanol was first developed by the British as a decontaminating and neutralizing agent against lewisite, it was designated "BAL," for the "British anti-lewisite," and this has become the generally accepted name.[7]

THE EXPERIMENTAL USE OF BAL

Great hopes for the clinical effectiveness of BAL (dimercaprol) were based on these theoretic considerations as well as on in vitro tests. These hopes were fully realized when BAL was shown to be effective in both laboratory animals and human beings. The effectiveness of the compound could be demonstrated in damage and poisoning due to arsenical agents of chemical warfare as well as to arsenical therapeutic agents.[8]

The following summary gives some of the important effects of BAL against arsenical damage:

1. In both laboratory animals and human beings the damage to the skin due to arsenical vesicant agents of chemical warfare could be prevented by the preceding application to the skin of BAL preparations.[9]

2. In both laboratory animals and human beings the damage to the skin produced by arsenical vesicant agents of chemical warfare could be arrested and probably even reversed by the local application of BAL preparations two minutes to two hours after exposure to the damaging agent.[10]

3. The systemic poisoning produced in laboratory animals by various arsenical agents, including oxophenarsine hydrochloride, could be effectively counteracted by BAL. This was shown by a significant reduction in mortality rate and a longer survival time of the BAL-treated poisoned animals accompanied with an increased urinary excretion of arsenic.[11] While this beneficial action of BAL in systemic poisoning could be achieved by application of BAL to the skin, the parenteral administration of the drug was much more effective.[11b]

4. In vitro experiments on trypanosomes and spermatozoa demonstrated that organisms which had lost their motility and showed early degenerative changes due to *arsenic poisoning regained their motility and their normal* appearance after addition of a dithiol.[12]

EFFECT OF BAL IN ARSENICAL DERMATITIS

Dermatitis produced by antisyphilitic arsenical drugs was first treated by inunction with BAL in England.[6] Later on, patients with sensitization dermatitis due to adamsite, an arsenical chemical warfare agent, were treated by inunction in this country.[13] Intramuscular injections of BAL were also used in England.[14] The most extensive series of patients with arsenical dermatitis treated with BAL is that assembled by Eagle.[15] This series included patients treated at the Rapid Treatment centers of the United States Public Health Service. In these cases BAL was given intramuscularly, either as a 5 per cent solution in peanut oil with benzyl benzoate, 10 per cent; or as a 10 per cent solution in peanut oil with benzyl benzoate 20 per cent.

In Eagle's series there were 88 cases of arsenical dermatitis, 51 of which were typical cases of exfoliative dermatitis. BAL "usually stopped the progression of the inflammatory reaction and accentuated the healing process." In his series the average time for definite improvement in the exfoliating conditions which responded to treatment (80 per cent) was three days, and the average time for almost complete recovery was thirteen days.[16]

Among the cases of arsenical dermatitis which did not respond to treatment with BAL (20 per cent), gluteal abscesses or cellulitis developed at the site of injection in 5 cases. No such complication developed in any of the other cases of arsenical dermatitis or of other BAL-treated arsenical complications (see following paragraphs).

In a previously reported series of 40 cases of arsenical dermatitis (these are obviously included also in the aforementioned later series of 88 cases), Eagle[17] noted a mortality rate of 5 per cent and discussed the factors influencing the effectiveness of treatment with BAL in arsenical dermatitis. He stated that initially after administration of BAL there was a subsidence of edema and inflammation of the skin, a decided fall in temperature and a striking subjective improvement. While the weeping of the lesions subsided, the painless exfoliation often progressed and in some cases appeared to be accelerated as the dermatitis healed. The impression was gained that the longer the duration of the dermatitis prior to administration of BAL, the longer the time required for definite improvement. Cases of mild dermatitis with only pruritus and erythema responded most quickly (in from twenty-four to forty-eight hours).

[7] Waters, L. L., and Stock, C.: BAL (British Anti Lewisite), Science **102:** 601, 1945.

[8] It was, of course, soon realized that BAL might be effective also against poisoning by other metallic compounds. This has been shown to hold true for mercury poisoning (Gilman, A.; Allen, R., and Phillips, F. S.: 1944, 1945.* Longcope, W. T., and Luetscher, J. A., Jr.: 1945*). The use of BAL has also been studied in poisoning due to lead, stibium, vanadium, bismuth, *cadmium* and zinc.[7] Except in the case of cadmium the results have not been unequivocal or particularly encouraging, but further investigations are still required.

[16] [illegible] cates that the improvement which BAL effects in exfoliative dermatitis and other cutaneous eruptions due to arsenical agents is associated with detoxification of the arsenic. Often, but by *no means always, there is an increased urinary excretion of arsenic* at the time when the dermatitis improves. Nevertheless, the possibility should be seriously considered that some of the improvement in these cases may be due to another effect of BAL, namely, the furnishing of large quantities of —SH groups as "building blocks" for the amino acids of the epidermis and other tissues (Peters, B. A.: Exfoliative Dermatitis Treated with Cystine, Lancet **1:** 264, 1945. Sulzberger, M. B., and Baer, R. L.: *Year Book of Dermatology and Syphilology*, Chicago: The Year Book Publishers, Inc., 1945, p. 99).

EFFECTS OF BAL IN OTHER COMPLICATIONS OF ARSENICAL THERAPY

In other complications of arsenical therapy treated with BAL Eagle[15] again reported the most extensive and up-to-date series of cases, which may be summarized as follows:

Toxic Encephalitis.—Of 55 patients, of whom 40 were either convulsing or in coma at the time of start of BAL therapy, 44 recovered completely within from one to seven days and 11 died. In some cases resulting in death, delay of therapy or too small a dosage of BAL appeared to be partially to blame for the result.

Agranulocytosis.—There were 11 cases, with recovery in 10 and 1 death.

Aplastic Anemia.—In 3 cases there was no beneficial effect from BAL.

Jaundice.—Of 14 patients, 5 showed prompt response to BAL, 7 evidenced no effect from BAL and there were 2 in whom the effects were debatable.

Massive Overdosing of Oxophenarsine Hydrochloride.—Of 4 cases, there were 3 with prompt response and 1 ending in death (the patient received too small a dose of BAL).

"Arsenical Fever."—There were 44 cases, with prompt recovery in all.

DOSAGE AND SIDE EFFECTS OF BAL

A considerable amount of work has been done in laboratory animals[17] and in human beings[18] on the effective dosage of BAL for treatment of arsenical dermatitis and other complications of arsenical therapy. On the basis of all available data Eagle[15] suggested the following schedule of dosage: In severe complications 3 mg. per kilogram is given in each injection (1.8 cc. of a 10 per cent solution of BAL for a patient weighing 60 Kg.). For the first two days six injections are given at four hour intervals; four injections are given on the third day and two injections thereafter for ten days or until complete recovery. In mild complications 2.5 mg. per kilogram is given in each injection (1.5 cc. of 10 per cent solution of BAL for a patient weighing 60 Kg.). For the first two days four injections are given at four hour intervals; two injections are given on the third day and one or two injections thereafter for ten days or until complete recovery.

Pharmacologic studies in human beings[19] have shown that side effects barely begin at the 2.5 to 3 mg. per kilogram level when four injections of this dose are given at four hour intervals on two successive days. The incidence of side effects increases rapidly when the dose is raised to 4 and 5 mg. per kilogram. All the side effects observed even at these higher dosage levels have been of a temporary nature. They included nausea, vomiting, headache, burning sensation of the lips, mouth, throat and eyes, pain in the teeth, lacrimation and salivation, muscular aches, burning and tingling of the extremities, feeling of constriction of throat and chest and elevation of systolic and diastolic blood pressure. These side effects usually are at their maximum at fifteen to twenty minutes after intramuscular administration of the BAL preparation.[19a]

When applied to the skin BAL is a primary urticariogenic agent (whealing agent), and cutaneous allergic sensitization to BAL does occur.[20] Thus far these effects have not in any case interfered with the use of the drug in the treatment of arsenical complications.

Barbiturates have been recommended as an antidote for the more severe side effects of BAL.

SUMMARY AND CONCLUSIONS

1. The history of the development of BAL is reviewed.

2. The studies of the important antiarsenical effects of BAL in vitro in laboratory animals and in human beings are summarized.

3. The action of BAL in counteracting the toxic effects of antisyphilitic arsenicals is reviewed.

4. The recommended dosage schedule for BAL is presented, and the undesirable side effects of the drug are listed.

5. It is pointed out that BAL was developed on the basis of a fundamental theoretic concept, which led to in vitro studies, indicating that it was able to compete successfully with thiol-containing tissue enzymes in attracting the poisonous metallic ion.

6. BAL has been proved of great practical value in preventing and counteracting many of the toxic effects of different arsenicals and of mercury. Its effects against many other metallic and nonmetallic poisons are not yet proved and require further study.

962 Park Avenue.

ABSTRACT OF DISCUSSION

DR. JUD R. SCHOLTZ, Pasadena, Calif.: As Dr. Sulzberger and Dr. Baer were among those who did fundamental work in the development of BAL, it is appropriate that they should have presented the subject to this section. It is apparent that this is a life-saving drug. Such a product puts a great responsibility on the physician. Prompt and accurate diagnosis and equally prompt and accurate treatment are serious obligations. It is likely that dermatologists will be more familiar with this drug than most of their colleagues in other branches of medicine. Therefore, we have a public relations job in our communities. We ourselves must become thoroughly familiar with this drug and see that it is popularized. We have in the past few months adequately demonstrated that this is a remarkable drug, inasmuch as it works in strange hands as well as in those of the men who developed it. With it we have saved several persons at the Los Angeles County Hospital in the last few months. Will Dr. Sulzberger tell us, please, how to obtain this drug? My associates and I have been unable to get it.

DR. HERMAN ALLINGTON, Oakland, Calif.: The development and use of this drug, as is true of penicillin, antimalarial drugs, the various fractions of blood plasma and insecticides, was greatly accelerated by the recent war. The authors have summarized the data on which this investigation was based and have shown step by step how it was carried through to a successful conclusion. I have been interested in BAL ever since early in the war, when it was made available for the prophylaxis and treatment of injuries from lewisite gas. At that time, its formula and mode of action were a carefully guarded secret. We were glad to have it but somewhat skeptical of its value. It is now apparent that when given early in adequate dosage, it is effective against certain types of heavy metal poisoning. From a canvass of the opinion of a number of men who have used it, I should judge that the incidence of local reactions, some of them severe, is somewhat greater than this paper would indicate. Further study, of the same excellent quality which led to the development of BAL, will probably soon lead to the discovery of similar but even more effective and perhaps less irritating medicaments.

* The incomplete references refer to reports which were secret, confidential or restricted at the time of presentation. Summarizing articles on BAL will appear shortly in the unclassified medical literature. (Since the preparation of this report several of these summarizing articles have appeared in the Journal of Clinical Investigation for July 1946.)

DR. JOHN G. DOWNING, Boston: I was called in consultation at 9:45 a. m. on April 27 regarding treatment of 2 young men. Each had been given 0.6 Gm. of oxophenarsine hydrochloride in a single dose, due to a mistake in the use of a hospital ampule containing ten doses for an individual injection. I ordered immediate shock therapy, including intravenous administration of dextrose and proper sedatives. Both men had been admitted to the hospital for treatment of early syphilis. After the injection they complained of a bad taste in the mouth; within a few minutes colicky pains developed in the abdomen, with nausea, retching and vomiting, and they suffered from chills followed by headaches. Evidence of toxic hepatitis with some degree of jaundice was present in each case. There was tenderness of the liver on palpation. At 10:45 a. m. they were given 3.5 cc. intramuscularly of BAL in peanut oil. Other supportive measures were continued, such as 10 per cent dextrose solution intravenously, 300 cc. of Parenamine, 5 mg. of vitamin K and 300 mg. of ascorbic acid. BAL, 1.8 cc. intramuscularly, was given every four hours for four doses the first day and twice daily for the four succeeding days. After four days, the gastrointestinal disturbances, which also included diarrhea, ceased, and at the end of eight days both patients were asymptomatic. I have the record of the several arsenic determinations made on the urine.

DR. STEPHEN ROTHMAN, Chicago: The detoxifying effect of BAL is impressively rapid and complete. In a patient in our department, severe arsenical dermatitis cleared up within three days after BAL was given. The most fascinating aspect of this dithiol compound is that its detoxifying action is considerably more than twice that of monothiol compounds. The reason for this potentiated action is that the spatial distribution of the two sulfhydryl groups in BAL is similar to the spatial distribution of sulfhydryl groups in proteins. Thus BAL is best suited to split off the arsenic from the protein molecules in which one arsenic atom has blocked two sulfhydryl groups. Historically it might be interesting to mention that in the twenties German authors praised the detoxifying effect of injections of cutaneous extracts ("detoxin") in arsenical and heavy metal poisoning. The effect of such extracts was obviously due to their sulfhydryl content.

DR. MARION B. SULZBERGER, New York: I want to thank the gentlemen for their remarks and to say that I agree with essentially everything they have said. Dr. Rothman's explanation is close to that given by the discoverers of this compound. Thompson and Stocken actually showed that when they treated kerateine with arsenic the arsenic was bound to the dithiols, i. e., to the compounds containing two sulfhydryl groups, so that in this respect Rothman's explanation is in entire agreement with their theory and with their experiments. As to Dr. Scholtz's question: As far as I can tell, BAL is not generally available as yet. However, one can still get it I believe. It may be obtained direct from Dr. Harry Eagle, at Johns Hopkins University School of Medicine, Baltimore. He will send it air mail, I am certain, if you telegraph when you have a suitable case. Moreover, I think that the Intensive Treatment centers that participated in the cooperative program of evaluating antisyphilitic schedules are supplied with BAL and that it can be obtained from them.

NOTE.—Since the date of this discussion, a preparation of BAL for intramuscular injection has been made available by Hynson, Westcott & Dunning, Inc., of Baltimore.

Nobel Prize Winners.—A study of the recipients of the Nobel Prize in physiology and medicine and in physics and chemistry in the *U. S. Naval Medical Bulletin* shows that in the forty-five years during which the prizes have been given the youngest recipient of the prize for medicine was Sir Frederick Banting, a Canadian, the co-discoverer of insulin. He was 32. Ferdinand Brisson of France was 86 and Jane Addams of Chicago was 74 when they received the Nobel Peace Prize.

NEPHRECTOMY FOR HYPERTENSION WITH UNILATERAL RENAL DISEASE

Report of Forty-Nine Cases

RIGDON K. RATLIFF, M.D.
REED M. NESBIT, M.D.
ROBERT T. PLUMB, M.D.
and
WAIT BOHNE, M.D.
Ann Arbor, Mich.

Increased arterial blood pressure occurs in patients having a variety of diseases. Some of these diseases can be demonstrated clinically by pyelography, and because of this fact pyelography is included in the routine study of hypertensive patients in the University of Michigan Hospital. Patients with hypertension also have electrocardiographic study, eyeground examination, orthodiagraphic study and study of total renal function. When the excretory urograms are unsatisfactory for diagnosis, cystoscopy with split phenolsulfonphthalein and retrograde pyelogram is done.

During the years 1940 to 1945 inclusive, 2,055 hypertensive patients were studied in the urologic clinic (table 1). This figure represents approximately 20 per cent of the total number of pyelograms (9,501) that were made during the six year period covered by this study. Over-all, there was an incidence of renal abnormalities of 8.9 per cent. It will be noted that in 1940 and 1941 there was an incidence of 15.1 per cent, as against 5.1 per cent in 1945. This means that the interpretation of the pyelogram in the early part of the study was more critical than that in 1945 or else that the incidence of abnormality in these early years was three times what it was in 1945. It seems more probable that the critical interpretation of the pyelogram rather than the incidence has changed. During this period all the pyelograms were read by the same man. The extent of this variation in interpretation is further emphasized when we find that Schroeder and Steele in 1941 reported an incidence of about 40 per cent, as compared with our incidence of 9 per cent. For any one then to postulate, without consideration of this variable, that the incidence of renal pathologic changes in the hypertensive patient is the same as that in the average adult is not justified.

TABLE 1.—*Hypertension (Pyelograms)*

Year	Pyelograms, Total No.	Not Indicating Abnormality or Inconclusive	Indicating Abnormality No.	Indicating Abnormality %
1940 and 1941	528	448	80	15.1
1942 and 1943	680	626	54	7.9
1944	378	353	25	6.6
1945	469	445	24	5.1
Total	2,055*	1,872	183	8.9

* 21.6 per cent of total pyelograms (9,501).

Our interpretation of the pyelograms is reported in table 2. One hundred and eighty-three lesions are recorded. This table shows that hypertension may coexist with any of the common renal lesions, but there

---

From the Department of Surgery, University of Michigan Medical School.

Read before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

is no consistent relationship between hypertension and any particular gross renal lesion. Congenital absence, reduplication of pelvis and bilateral lesions occurred in 70 of the patients. The remaining 113 patients had unilateral lesions. The matter of interpretation is here again important. In all categories there is a consistent incidence of lesions throughout the years of study, with the one exception of pyelonephritis. The ratio for this condition is 15.5, 15.5, 7.5, 7.5, 6 and 3. One cannot well believe that there were five times as many cases of pyelonephritis in 1940 as in 1945. It must follow then that the interpretation favored the lesion more in earlier years than now.

Of the 2,055 pyelographic studies carried out on hypertensive patients during the period from 1940 to 1945, approximately 1,350 were made solely in an effort to determine a possible renal cause for hypertension, for that number of patients had no symptoms or urinary findings which alone would have indicated the need for urologic studies. The cost of making pyelographic studies is considerable. If some means of selection could be employed so that pyelography could be eliminated from the routine examination and employed in only selected cases, then a great economy could be effected. That method, however, is not now available

As stated, only 9 per cent of all the patients studied had abnormalities, while less than 5 per cent were candidates for nephrectomy and fewer came to operation Because of our low incidence of demonstrable surgical renal defects in hypertensive patients and because some authors have expressed pessimism with regard to the result of operation in such cases, an evaluation of nephrectomy in hypertension is needed and justified.

During the eleven year period 1934 to 1945 in the records of the University Hospital 49 cases of severe hypertension treated by nephrectomy were found. In all but 7 of these the systolic pressure was well over 200 or the diastolic over 100. The follow-up record has been longer than twelve months in all but 8 of the cases.

Table 3 summarizes the results of nephrectomy in these 49 cases. Seventeen patients (34.6 per cent) were considered to have had good results, and 6 (12.4 per cent) were improved; results in 26 (53.0 per cent) were failures. A good result means that the patient was free from hypertensive symptoms and had a normal blood pressure at the time of the last follow-up report. In other words, the patient is considered cured according to clinical evidence at the date of check-up examination. Results were regarded as a failure when a patient was not improved by nephrectomy or had subsequently died a hypertensive death.

An analysis of the 49 patients shows that 17 had no symptoms of the urinary tract or abnormalities of the urine as determined by simple clinical examination. The remaining 32 had some complaint or abnormality referable to the urinary tract. It is thus evident that no simple clinical test can be used to select the patients most likely to have pyelographic abnormalities; all must be examined by urographic studies.

There were 19 cases of unilateral chronic pyelonephritis with hypertension (table 4). Eight of the patients had atrophic pyelonephritis, sometimes termed congenital hypoplasia. Inasmuch as all the patients with so-called hypoplasia in this group showed microscopic evidence of the inflammatory changes, it is questionable that these are true examples of congenitally undeveloped kidneys. It seems more probable that the lesion represents an arrest of growth due to inflammatory changes occurring in the small kidney of the infant, for the majority of the patients are known to have had infections of the urinary tract during early childhood. In some instances the infective process appears to have burned itself out during childhood, while in others the inflammatory process has been a prolonged one. This type of lesion might well be termed infantile chronic pyelonephritis, in contrast to the adult type of pyelonephritis, in which atrophic changes occur but never the dwarfed kidney that follows infections acquired during childhood. In this group, 2 of the patients remained free from hypertension following nephrectomy and 2 are improved, while 4 showed no change. The 11 patients with chronic pyelonephritis without hypoplasia fared better after nephrectomy: 5 had good results, 1 was improved and there were 5 failures. One of the cases in this group is outstanding and should be reported in its details.

A. B, a man aged 41, was admitted to the University of Michigan Hospital on Oct. 14, 1938, complaining of hypertension with headaches for three years and shortness of breath with dyspnea on exertion for a year. He has had gross hematuria on two occasions, five months and one month prior to his admission to the hospital. Examination was essentially noncontributory except for the following factors: The blood pressure was 200 systolic and 110 diastolic; the heart was enlarged, and the eyegrounds showed hemorrhagic and exudative retinitis and mild hypertensive retinitis. The urine was normal. Excretory pyelograms showed a normal left kidney but nonvisualization on the right. Retrograde pyelograms revealed a normal left kidney and advanced changes characteristic of advanced chronic pyelonephritis on the right.

Nephrectomy on the right side was performed Nov. 11, 1938. The pathologist reported "dilation of the renal pelvis; inflammatory infiltrations beneath the pelvic mucosa; extreme sclerosis of the arterioles, and arteriosclerotic nephropathy with advanced pyohydronephrotic atrophy." The postoperative course was uneventful, and at the time of discharge from the hospital, on his fifteenth postoperative day, the blood pressure was 135 systolic and 80 diastolic.

He has been seen on numerous occasions during the eight years that have elapsed since nephrectomy, and on each occasion he has reported freedom from all hypertensive symptoms. One year following operation his blood pressure was 130 systolic and 86 diastolic, and at that time the eyegrounds were reported to be free from hemorrhages and exudates. The most recent check-up examination was made in July 1945. At that time the blood pressure was 130 systolic and 80 diastolic, the eyegrounds were normal and the patient reported that he was symptom free and working every day.

Nephrectomy was performed on 11 patients who had hydronephrosis with significant hypertension. Five of them had no permanent lowering of the blood pressure following operation, while 2 have had moderate improvement and 4 have had normal blood pressures that have persisted since operation. Two of the latter are significant in that they were known to have had normal levels of blood pressure prior to the development of advanced hydronephrosis and were followed for a time during which the development of hypertension paralleled the development of advancing hydronephrosis. In each instance nephrectomy was followed immediately by a return of the blood pressure to normal. Both of the patients were students at the University of Michigan and were followed at the University Health Service and the University Hospital during the entire cycle of the illness.

The remarkable improvement that ensued following nephrectomy in 3 of 7 patients who had calculous pyonephrosis and coincidental hypertension was as unexpected as it was gratifying. Also, 1 patient who is considered to have been improved but not cured has enjoyed a most spectacular regression of the hypertensive symptoms which had incapacitated her prior to nephrectomy.

CONCLUSION

Chronic arterial hypertension can be of renal origin. When unilateral renal disease is demonstrated by roentgenologic examination it can be treated by nephrectomy, with an expectation of improvement or cure of the associated hypertension in about half of the cases.

In the present series of cases the greatest incidence of favorable results occurred in the cases of adult chronic pyelonephritis, hydronephrosis and calculous pyonephrosis. In the group of cases termed "infantile chronic pyelonephritis" by us, the incidence of cure is definitely less than that in the adult type.

Routine urologic studies in all hypertensive patients, regardless of the high over-all cost entailed, appear to be desirable for the reason that a significant number of the patients having gross renal lesions could not otherwise be discovered.

ABSTRACT OF DISCUSSION

Dr. Alfred I. Folsom, Dallas, Texas: The interpretation of the so-called atropic or hypoplastic kidney is difficult clinically, since the pathologists themselves are divided as to whether a specimen shows true hypoplasia or true atrophy of the kidney. There are certain definite criteria which have helped me to differentiate between the hypoplastic kidney and the pyelonephritic atrophy. One is the arrangement of the calices. In the hypoplastic kidney, the ureter goes up in the pelvis and then there is a small group of calices and infundibula which run almost parallel, almost like a cluster of roses; this is totally different from the picture of pyelonephritis, in which there is the uniform distribution of the calices, of slope from the upper pole to the lower pole; in the cases of atrophy from inflammation this same arrangement of the calices is maintained, whereas the true hypoplastic kidney has this group of calices more or less bunched together, like a bunch of roses. The only constructive suggestion which I should like to make with reference to the evaluation of the kidney that may be potentially the cause of hypertension is that developed by aortography. When Gus Santos first brought out his epoch-making paper, it shook me like an earthquake. We have recovered from our first terrible shock and fear of this method, so that I have done several of these aortographic investigations myself. We are now, with reference to that subject, much like Gil Thomas and Bill Braasch and I were many years ago in interpreting pyelograms. However, I think that if a sufficient number of us get interested in it and do a large enough number, there may come out of it a much clearer interpretation than now exists. In aortography in this particular type of case we have a means of helping to determine whether this kidney should be removed, with the idea of the blood pressure being affected. This method will help pick out the patients who will be relieved by this operation; as evidenced by this frank report, only about half of them, even in 49 cases out of over 2,000 that we have investigated, were actually helped. The criterion which I think is sound is that a diminution in the caliber of the renal artery and an insufficiency of the circulation of the kidney are demonstrated. That is probably one of the soundest bases and one of the most valuable contributions that this nerve-racking procedure may contribute to this interesting subject.

Dr. William J. McMartin, Omaha: I wish to compliment Dr. Ratliff for the study of the largest number of hypertensive patients examined urologically in one institution to determine whether or not there was present unilateral renal disease acting as the generator of hypertension. Unilateral renal disease as the sole cause of hypertension is rare. In 1942, I reported with McCurdy 4 cases of hypertension, in which we were able to get good results following unilateral nephrectomy. The first patient had a blood pressure of 240 systolic and 130 diastolic. He had had a calculus removed from a kidney a number of years before. His preoperative symptoms were attacks of blindness with severe headache. We removed an atrophic, infected kidney. His blood pressure fell to 140 systolic and 90 diastolic and averaged this pressure for four years. He worked every day for three and one-half years, when a coronary attack developed and he died. The second case was that of a postmaster with a blood pressure varying from 170 systolic and 100 diastolic to 186 systolic and 110 diastolic. His complaints were attacks of abdominal distention and pain in the back. Urologic examination revealed unilateral hydronephrosis and hydroureter, with pyelonephritis. Nephrectomy was performed. The blood pressure following operation remained at 150 systolic and 90 diastolic. This patient lived for three years after the operation and died suddenly of a coronary attack. The other 2 cases were those of men in the third and fourth decades, both with malignant hypertension of over 200 systolic and with diastolic pressures varying from 100 to 140. One had pyelonephritis with early sclerotic thickening in the renal arterioles. The other patient had a more advanced pyelonephritis, with some scarring of the renal parenchyma. Nephrectomy on both of these men brought pressures to normal, and they have stayed normal for five years. Dr. Ratliff and Dr. Nesbit have found that out of 2,055 patients with hypertension 1,350 patients had no urinary findings which might indicate a need for urologic study. Out of the 1,350 cases, I hope that he will tell us how many patients showed unilateral renal disease and how many of these came to nephrectomy with successful results. The fact that only 9 per cent of these patients had abnormalities and that less than 5 per cent of these came to nephrectomy should impress all of us that though those patients are amenable to successful treatment it is a rare happening. We are finding repeatedly a note of pessimism in most of the reports, be they of a clinical, operative or experimental nature. Pessimism with regard to surgical treatment of the diseased kidney in these patients is not fully warranted, because cure or improvement may be expected in 50 per cent of these patients able to come to operation.

DR. RIGDON K. RATLIFF, Ann Arbor, Mich.: We have had no experience with the aortogram in the differential diagnosis of pyelonephritis. As to the final disposition of the 2,055 hypertensive patients studied by pyelography, it was pointed out that less than 5 per cent were candidates for nephrectomy and fewer than this percentage came to operation. Those who did come to operation are included in the series of 49 cases, details of which are presented in the paper. It is obvious in this survey that the higher percentage of cures falls in that group of patients who have gross urologic symptoms. Fewer good results followed nephrectomy in the group of hypertensive patients who had no urinary symptoms.

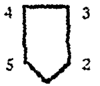
USE OF 5-NITRO-2-FURALDEHYDE SEMICARBAZONE IN DERMATOLOGY

JOHN GODWIN DOWNING, M.D.
MILLARD C. HANSON, M.D.
and
MARION LAMB
Boston

In a search for an effective agent against both gram-positive and gram-negative pathogenic bacteria invading the skin, the possible value of a nitrofuran was brought to our attention, namely, that of Furacin Soluble Dressing.

NITROFURANS

Chemistry.—The furans are chemicals obtained for the most part from oat hulls. Furfural, the fundamental member of the furan series for the synthesis of other derivatives, results from the dehydration of sugars of five carbon atoms, known as pentoses, present in the natural product. The furans are five-membered heterocyclic ring compounds of this type of formula and numbering systems:



The stability of furan derivatives varies depending on the substitutes present in these numbered positions. Many simple furans are sensitive to acid but stable to alkali. The introduction of a group in the 5 position produces a compound with more stability in respect to acid mediums but diminished stability in respect to alkaline environment. Much work has been done and interest displayed in furan chemistry, but in spite of this there is much fundamental work to be done to further the chemical knowledge of these compounds. Therapeutic applications of furan compounds have been extremely limited.

Bacteriostatic Action.—The in vitro bacteriostatic and bactericidal action of furan derivatives was shown by Dodd and Stillman to depend on the presence of a nitro group in the 5 position.[1] Antibacterial activity was exhibited by the 5-nitro derivatives of a series of simple furan derivatives. This activity extended to a variety of gram-positive and gram-negative bacteria.

The proved antibacterial properties of the nitrofurans, demonstrated in vitro, suggested their possible use in the treatment of wounds. Among others, 5-nitro-2-furaldehyde semicarbazone (Furacin) was found to be nonirritant and nontoxic on local application and to exhibit no adverse effect on the healing of experimental wounds. Because of its antibacterial properties, it was suggested for clinical trial. Subsequently, Meleney, Johnson, Pulaski and Colonna called attention to the desirability of further study of this particular nitrofuran because of its action against gram-negative bacteria.[2]

Furacin (5-nitro-2-furaldehyde semicarbazone) is a lemon yellow crystalline compound having a slight solubility in water (1:4,200) and more solubility in compounds of the glycol type—propylene glycol (1:300) and Carbowax 1500 (1:100). It is heat stable at an autoclave temperature of 120 C. but decomposes at temperatures above 227 C. Exposure to light causes some discoloration. It is effective as an antibacterial agent in the presence of blood and serum. In a study of the mechanism of action of nitrofurans against bacteria, Dodd and Cramer found that 5-nitro-2-furaldehyde semicarbazone, depending on concentration, could prolong the lag phase of bacterial action or, at higher concentrations, exert bactericidal action.[3]

Furacin Soluble Dressing is a 1:500 solution of 5-nitro-2-furaldehyde semicarbazone (Furacin) in a water-soluble vehicle containing Carbowax 1500 and propylene glycol. This preparation was employed in the treatment of infected war wounds in a preliminary study by Snyder, Kiehn and Christopherson.[4] Clinical improvement was correlated with reduction in the bacterial flora. Early deodorization and a clean appearance were observed. Further clinical studies are in progress and will appear in the literature.

Toxicity.—The toxic effects of 5-nitro-2-furaldehyde semicarbazone have been studied in mice, rats, monkeys and human beings. The oral lethal dose of 50 per cent of mice treated (LD_{50}) was found to be 0.58 Gm. per kilogram. For rats, the oral lethal dose of 50 per cent is 0.59 Gm. per kilogram when given orally and 3 Gm. per kilogram when given subcutaneously. Monkeys fed 0.3 Gm. daily for five weeks showed no effects on body weight, electroencephalogram, blood cell counts, renal and hepatic histology or electrocardiogram. Finally, 10 human subjects have ingested this compound, some in doses of 4 Gm. daily for three days and others in doses of 1 Gm. daily for forty-nine days. Nausea was the only reaction observed and occurred in about 20 per cent of patients; of these patients, 8 per cent continued to react by vomiting. One decided sensitization reaction was observed on oral administration of the drug to a patient who had previously received local treatment with 5-nitro-2-furaldehyde semicarbazone dressing for a prolonged period.

Irritant and Sensitizing Properties.—The irritant and sensitizing properties of the dressing and the soluble

base were studied by patch testing. Two hundred normal persons were patch tested for irritant properties, and ten days later 50 of them were retested for sensitizing properties. The test substances were applied to the skin for forty-eight hours, and the reactions were noted at twenty-four, forty-eight, seventy-two and one hundred and twenty hour intervals. The substances were applied under a 1 inch (2.5 cm.) square piece of cotton fabric, which was covered with oil silk and secured by adhesive tape.

In no instance was there a reaction characterized by erythema with edema, vesiculation or ulceration. The first application of the dressing resulted in erythema reactions (1 plus) in 1.5 per cent of the subjects in twenty-four hours, in 5.5 per cent in forty-eight hours, in 1.5 per cent in seventy-two hours and in no subjects in one hundred and twenty hours. Reactions to the soluble base test occurred in 0.5 per cent at twenty-four hours, in 3.0 per cent at forty-eight hours and in none at seventy-two and one hundred and twenty hours. The second twenty-four hour application resulted in 4.0 per cent reactions in forty-eight hours to the dressing and in 2.0 per cent to the soluble base in the same period.

Photosensitization was not observed. Three subjects were given erythema doses of ultraviolet radiation over the soluble dressing without reactions. The discoloration occurring when the compound was exposed to sunlight apparently did not affect its value. There was no staining of the skin.

DISEASES TREATED AND RESULTS

Two hundred and twelve patients were placed under treatment. The diseases treated have been grouped in conformity with the 1942 "Standard Nomenclature" of the American Medical Association (table 1). In evaluation of the clinical response to the dressing, Meleney's classification has been adopted, the results being divided into four groups: brilliant, good, questionable and no effect.[5] According to Meleney, the usefulness of a therapeutic agent without controls cannot be proved unless the majority of results are either brilliant or good.

Group 1.—Infectious Eczematoid Dermatitis: This group included the infectious eczematoid dermatitis of the legs described by Engman,[6] that of the hands described by Lane and associates,[7] streptococcic dermatitis of the ear described by Mitchell,[8] secondarily infected eczematoid dermatitides surrounding ulcers and dermatophytosis. Of 26 cases remaining under observation, the results were brilliant in 6, good in 14 and questionable or nil in the rest. The longest period of treatment of healed patients was eighteen days and the shortest four days, with an average of 8.6 days. Treatment consisted in application of the dressing twice daily. In the cases of favorable results, the weeping and crusting diminished strikingly in twenty-four to forty-eight hours, with abatement of burning and itching. Temporary irritation was noted in 2 of the 5 patients not responding to treatment.

Ecthyma: Of the 12 cases of ecthyma remaining under observation, the therapeutic response was good in 9 cases and questionable or nil in 3. Four applications were made daily. In 3 cases 5 per cent ammoniated mercury ointment was used for comparison; the response to the two agents was equally good.

Impetigo Contagiosa: Forty patients with this disease were treated, with 26 remaining under observation. Applications were made four times daily, without covering except when necessary to protect the clothing. The result was classified as good if the lesions were healed on the patient's return to the clinic after one week of treatment. This response was obtained in 20 cases; the results were questionable in 3 cases and nil in 3. It was found that a light covering, such as a handkerchief, secured over the face eliminated the dark brown discoloration of the dressing caused by exposure to light and kept the solution in the proper place.

Case 1.—J. C., a 53 year old man, was first seen on Dec. 14, 1945 Fifteen days previously he had noted a small sore on the left side of his face This was diagnosed by an attending physician as impetigo. Treatment at that time produced an irritation Subsequent application of penicillin ointment resulted in a severe eczematoid reaction, with pronounced weeping and crusting over the left side of the face and neck. Burning and itching were severe. Treatment with 5-nitro-2-furaldehyde semicarbazone dressing applied twice daily was initiated. The following morning the patient reported that he had his first night's sleep in two weeks; the weeping had ceased, and the crusting had diminished. On the fifth day the patient's condition was decidedly improved, and in eight days the face was healed

This case illustrates the value of an additional therapeutic agent (fig. 1).

Sycosis Vulgaris: Only 3 patients with sycosis vulgaris were treated. The result was good but temporary in 2 and questionable in 1.

The number of cases in the rest of group 1 is too small to permit of the drawing of conclusions.

Group 2.—Dermatophytosis: Five patients with dermatophytosis with secondary infection were treated. In 2 the secondary infection was relieved, but the fungous infection persisted in all cases.

Group 3.—Dermatitis Venenata: There were 9 cases of dermatitis venenata with secondary infection. All the patients showed rapid improvement of the secondary infection, but later the underlying dermatitis became irritated.

Group 4.—Ulcers: Twenty-four patients with ulcer—traumatic, postoperative or decubitus—were treated. The majority of responses were brilliant or good. One of the postoperative ulcers developed after a Linton flap operation for vascular disturbance in a lower extremity. The ulcer, which extended along the entire incision, was 5.0 cm. in width, with an uneven base and irregular edges, and was discharging profusely. The bacterial flora included Staphylococcus aureus, Streptococcus haemolyticus and Pseudomonas aeruginosa. The distinct odor disappeared in forty-eight hours, and the discharge was controlled in seventy-two hours. The second postoperative ulcer, which was 6 cm. in diameter, showed a nearly pure culture of Ps. aeruginosa. It had been unresponsive to gentian violet medicinal, dilute acetic acid and chlorine preparations. The response to 5-nitro-2-furaldehyde semicarbazone dressing was prompt, and the cultures were sterile on the fifth day.

Three patients were treated for decubitus ulcer. Their underlying medical problems were subacute bacterial endocarditis, diabetes mellitus and malignant growth of the gastrointestinal tract. The patient with subacute bacterial endocarditis had an ulcer over the sacrum 8 cm. wide, with a deep crater, uneven base and irregular edges. The dressing was applied twice daily. Even though the patient's general condition was poor, the ulcer promptly became clean and was epithelized in twenty-two days. The patient died on the twenty-fourth hospital day. Autopsy showed no evidence of toxic effects of the dressing. The ulcers of the diabetic patient were extensive, involving large areas over the sacral and lumbar areas, and extended to the flanks. There was also a large abscess in the right popliteal space. The ulcers were dressed twice daily, and 60 Gm. of the dressing was injected into the abscess once daily for seventeen days. The patient died of diabetes on the seventieth hospital day. The dressing controlled the odor and caused a diminution in the discharge. There was no evidence of irritation of the tissues. Autopsy revealed no findings suggestive of toxicity of the dressing. There was no follow-up on the third case.

Group 5.—Group 5 was wholly composed of cases of hypostatic ulcer, of which there were 29, with 25 patients remaining under observation. The response was brilliant in 4 cases and good in 14. Three patients were hospitalized with rest in bed; the rest were ambulatory. No supportive measures such as elastic bandaging or stockings were used. Two patients were operated on for improvement of circulatory disturbances after ulcer infection had been controlled. The longest period of treatment was one hundred and twenty-nine days and the shortest forty days. In all cases the odor and discharge disappeared within from two to seven days. Occasionally a patient complained of a mild burning on application of the dressing, but this lasted for only a few minutes and was not intense enough to warrant discontinuance of the treatment. In 3 cases in which the dressing controlled the infection preparatory to skin grafting, it was also used after grafting. The percentage of takes was comparable to that with other accepted methods. There was no evidence of interference with epithelization or granulation.

The following cases illustrate the correlation of bacteriologic and clinical findings:

Case 2.—A. K., a 47 year old woman, was treated in the hospital during February 1945, with elevation, compresses and diverse topical applications, without favorable response. On readmission on Oct. 15, 1945, the ulcers had enlarged, despite treatment in the dispensary, and involved one fourth of the anterior and lateral aspects of the lower part of the left leg. There was a profuse discharge. Cultures grew Staph. aureus, Str. haemolyticus and Ps. aeruginosa. A Hinton test of the blood elicited a negative reaction. Use of the dressing resulted in rapid control of the discharge, and the ulcers showed a clean granulating surface. On December 10 a Linton flap operation for improvement of circulation was performed, and the dressing was employed postoperatively. On Feb. 26, 1946, the patient was discharged with the ulcers healed except for an area measuring 0.8 cm. in width, which was reported healed two weeks later. The length of treatment was one hundred and twenty-nine days. There was no interference with granulation or epithelization. Although extensive denuded areas were dressed over a long period, there was no evidence of toxic effects from absorption (fig. 2).

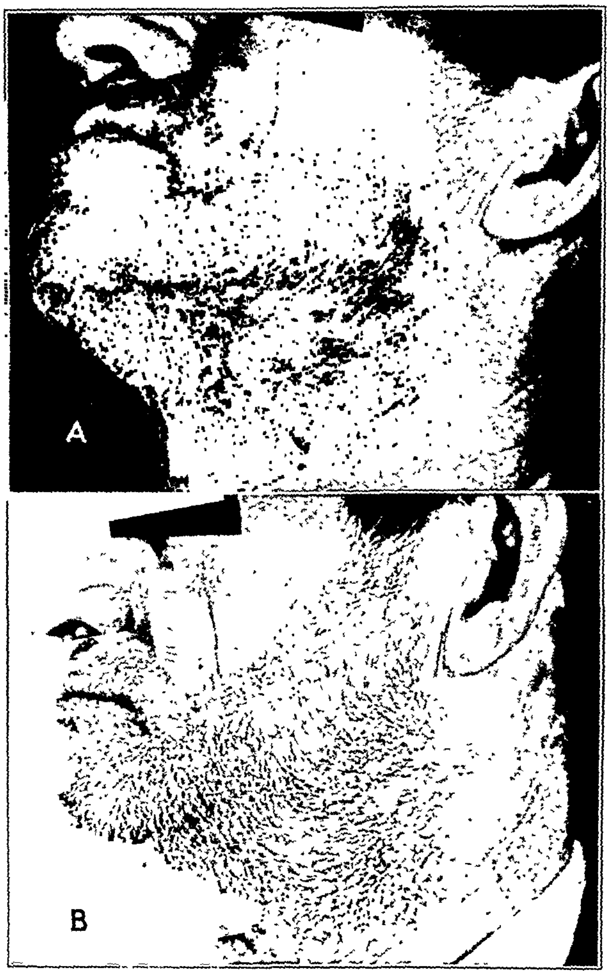

Fig. 1 (case 1).—*A*, severe pustular and eczematoid dermatitis in J. C. following treatment of impetigo with penicillin ointment. *B*, appearance five days later, after use of Furacin Soluble Dressing.

Case 3.—J. N., a 65 year old man, was referred by the Surgical Clinic with a treatment-resistant hypostatic ulcer and eczema of the right leg of four months' duration. The ulcer measured 1.5 cm. in its greatest width, the edges were sharply demarcated and there was a slight discharge. A Hinton test of the blood elicited a negative reaction Daily applications of the dressing were made, and the leg was healed forty-two days later. The bacterial flora included Staph aureus, Staphylococcus albus, Str haemolyticus, diphtheroids and enterococci Cultures showed the strains to be sterile in four, eight, four, eight and one days respectively.

Group 6.—Acne Vulgaris: Of the 5 cases of acne vulgaris remaining under observation, the response was questionable in 3 cases and nil in 2. No irritation was observed.

Diabetic Ulcer: Three patients with diabetic ulcer were treated. The results were good in 2 cases and questionable in 1. There was no irritation.

Group 7.—The patients in this group were treated in some instances for control of secondary infection and in others, such as pemphigus, to ascertain the effectiveness of the dressing. The underlying conditions were not favorably affected. In 3 cases of psoriasis a definite local irritation resulted, which receded promptly on discontinuance of the treatment. The same phenomenon occurred in 2 cases of nummular eczema.

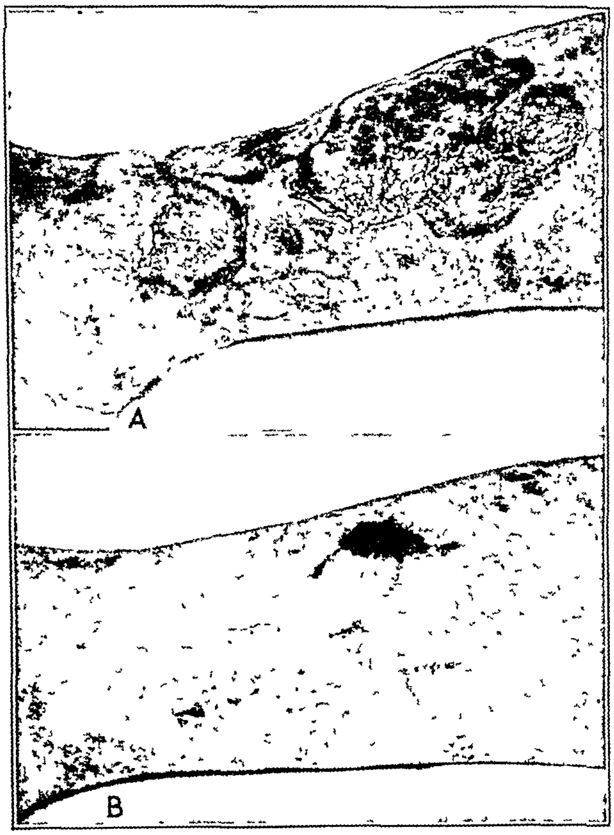

Fig. 2 (case 2) —*A*, ulceration of A K treated with Furacin Soluble Dressing from Oct 5, 1945 to Dec 10, 1945. A Linton flap operation was performed, and dressing was used postoperatively. *B*, result on discharge from hospital, Feb 26, 1946

BACTERIOLOGY

Cultural studies of the bacterial flora were made in 29 cases. As shown in table 2, eighty-seven strains of sixteen species of organisms were isolated. The gram-positive organisms Staph. aureus, Staph. albus, Str. haemolyticus, Corynebacterium diphtheriae and diphtheroids represent 81.6 per cent of the total cultures. Of the gram-negative organisms, Proteus vulgaris and Ps. aeruginosa were the most frequent. Only two strains of Escherichia coli were noted.

All specimens were cultured aerobically and anaerobically. All were plated in a uniform manner, and rough estimates of the number of colonies were made. The symbol 4 + indicates a heavy confluent growth, 3 + a heavy but not confluent growth, 2 + moderate growth and 1 + scant growth. Cultures were not considered reduced unless there was an appreciable reduction in the number of colonies, that is, from 4 + to 2 + or less or from 3 + to 1 +.

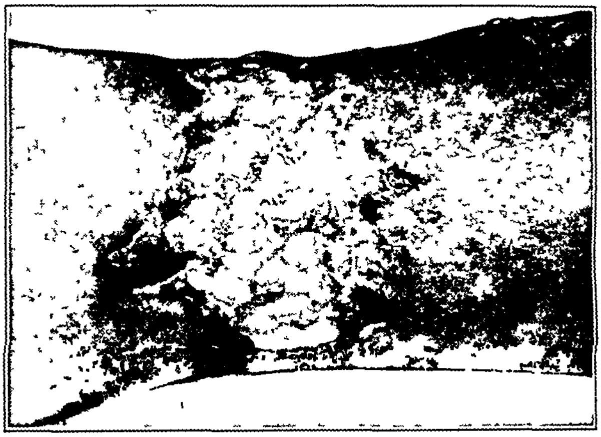

Fig 3 (case 3) —Successful pinpoint graft in which Furacin Soluble Dressing was used for the treatment of ulcer and subsequent dressing of graft.

Subcultures were made at the time of planting in order to eliminate the possibility of bacteriostatic action of any of the drug carried from the dressing.

Virulence tests were done on all C. diphtheriae. One was found to be virulent. The coagulase test was done on all staphylococcus cultures (table 2).[9]

The number of gram-negative organisms recovered from the cases included in this study was surprisingly small. In only 7 of the cases did we feel that the gram-negative organisms present were significant. In the 2 cases in which Esch. coli was present, 1 a case of decubitus ulcer, there was a heavy growth of P. vulgaris plus Klebsiella pneumoniae type B and Escherichia communior, all of which disappeared in three days. The other strain of Esch. coli was cultured from a traumatic ulcer which originally showed Str. haemolyticus and Staph. aureus. The Staph. aureus disappeared in two days, but Str. haemolyticus remained throughout. As the Esch. coli recovered in this case appeared in only

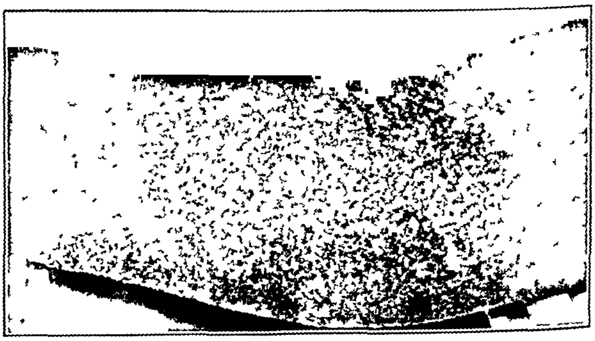

Fig. 4 (case 4) —Patch test reaction to soluble base on patient (E M.) who had used Furacin Soluble Dressing for treatment of persistent ulcer from Oct. 17, 1945 to Feb 7, 1946, at which time he suffered an intense sensitization dermatitis of the legs There was a positive reaction to the compound also demarcated and there was a slight discharge. A Hinton test of the blood elicited a negative reaction Daily applications of the dressing were made, and the leg was healed forty-two days later. The bacterial flora included Staph aureus, Staphylococcus albus, Str haemolyticus, diphtheroids and enterococci Cultures showed the strains to be sterile in four, eight, four, eight and one days respectively.

COMMENT

Furacin (5-nitro-2-furaldehyde semicarbazone) appears to be a useful addition to the armamentarium of therapeutic agents, and further studies with it should be done. Its efficacy in the control of gram-negative as well as gram-positive organisms makes it particularly useful in the treatment of ulcers.

Three deaths occurred in patients who had been treated with this dressing Autopsy of the first 2 patients failed to reveal any findings suggestive of toxicity from absorption, even when the drug was used in large amounts over extended periods. The underlying cause of death in these cases was diabetes millitus in the first and subacute bacterial endocarditis in the second. The cause of death in the third case (in which autopsy was not done) was cerebrovascular accident.

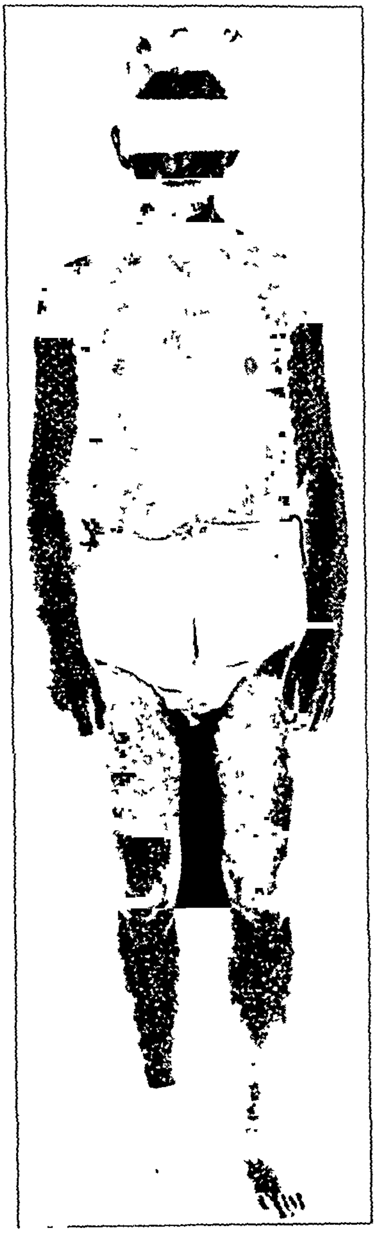

Fig 5 (case 5).— Local and generalized sensitization occurring in F K. on the twenty ninth day after the use of Furacin Soluble Dressing on ulcer and eczematoid dermatitis of the ankle.

It has been our opinion that a great discrepancy exists in this study, owing to the fact that control studies could not be made on absorption from the tissues because of the unavailability of methods for such determinations. Methods for this purpose should be developed in order to gain definite knowledge of possible toxicity from the continued use of this compound in large quantities.

Experience with different lots of 5-nitro-2-furaldehyde semicarbazone dressing indicates an imperative need for stabilization of the preparation per se and suggests the need of further studies with the soluble base in order to provide a stable vehicle. The property that the soluble base possesses of liquefying at low temperatures assures its reaching all parts of the affected area and makes possible the injection of it into abscesses and sinuses. On the other hand, the fact that the dressing liquefies at body temperature makes its control difficult. Further studies should be made for the purpose of developing a base with a higher melting point, a desirable property in the treatment of the type of patients that are covered in this report.

As regards the study of the irritant and sensitizing properties of this compound, a point made by Underwood and Gaul deserves consideration.[10] They have drawn attention to an important point in the discrepancies that sometimes occur between the reactions resulting from patch testing normal persons with a cutaneous drug and those resulting from its clinical use.

As regards testing cutaneous drugs on normal skin, we agree with Underwood and associates that the present methods of testing are of little value, a fact that we discovered in the latter part of our clinical studies. These writers expressed the opinion that a cutaneous drug may be safe for a normal skin but not for a damaged one. In stressing the need for defining methods of testing cutaneous drugs, they wrote as follows:

> Letters arrive weekly from manufacturers stating that their product was tested by an eminent authority and found safe. This is true for the normal skin, whose protective barriers (the p_H, the lipoid coating, the horny mantle) withstood the twenty or forty-eight hour contact; but what about a week or two week contact and, crucially important, the effects of the product on a skin shorn of its protective mantles or eczematized? The product in contact with living epidermal cells, nerve corpuscles and the cutis can be violently toxic, yet harmless when outside the cutaneous protective barriers The history of this or that remedy helping for a few days, followed by a sudden flare-up, has been consistently noted

The introduction of a new drug is a hazardous undertaking for the clinician. First of all, he has no control over the advertising and detailing of the product. Second, he has no assurance that the compound that he tests will be the same six months later, an assumption which is being investigated in the case of the product under discussion. There were practically no reactions until January 1946, when reactions began to appear, not only in our own patients but, as we were informed, in patients treated by the drug purchased in the open market. Last, despite the fact that the clinician recognizes the limitations of the drug and stresses its indications and contraindications, these warnings are likely to be disregarded by the medical profession and the laity, and what relieves one cutaneous disturbance will be used in the treatment of an eruption because it resembles the previous one. The establishment of the Therapeutic Trials Committee for the purpose of adequate and critical investigation of therapeutic properties and the safety of new agents will relieve the clinician of this responsibility.[11]

SUMMARY

1. Two hundred normal volunteers were patch tested with 5-nitro-2-furaldehyde semicarbazone and its soluble base, with results that would indicate little or no sensitization of normal skin.

2. Two hundred and twelve patients have been treated with this compound in a soluble base.

3. The drug does not interfere with granulation or epithelization of ulcers.

4. There is no clinical evidence of toxicity from absorption of the drug when it is used in large amounts over long periods.

5. Studies of cultures showed a high percentage of control of gram-positive and gram-negative strains by the drug.

[10] Underwood, G. B; Gaul, L. E; Collins, E, and Mosby, M: Overtreatment Dermatitis of the Feet, J. A. M. A **130**: *249 256 (Feb 2)* 1946.

[11] The Therapeutic Trials Committee, Report of the Council on Pharmacy and Chemistry, J. A M. A. **131**: *596 597 (June 15) 1946*

6. The drug has value in the treatment of superficial infectious eczematoid dermatitides but must be used carefully, owing to the danger of producing sensitization.

7. Although the drug is capable of sensitizing abnormal skins, in our experience to date this tendency is less than that of sulfathiazole or penicillin when used for topical application. However, in inexperienced hands the percentage of reactions may be greatly increased if the drug is used in subjects affected by mycotic infection or by industrial chemicals.

8. The drug shows excellent possibilities in the treatment of superficial infection of the skin, such as impetigo and ecthyma.

9. According to Meleney's classification, this drug has been found to be of value in the treatment of cutaneous diseases due to infection with lower organisms and ulcers resistant because of secondary infection. No therapeutic value has been demonstrated in fungous infections, industrial dermatoses, acne vulgaris and other miscellaneous dermatoses, such as psoriasis and pemphigus.

ABSTRACT OF DISCUSSION

DR. J. GARDNER HOPKINS, New York: Evaluation of an agent for local antiseptic action demands that it be effective and also harmless. Often the opinion of a careful observer on these points is, I believe, of more value than statistics. I give great weight to Dr. Downing's opinion as to this compound, which he has studied carefully, but I can only discuss his evidence, which as to harmlessness is admittedly confused. If these severe and generalized reactions occurred only in patients who were previously eczematized, then the drug may be useful in other groups of patients. If these reactions were due to a defective lot of material, they may be prevented by improved manufacture. If they are unavoidable, then occurrence in 3 per cent of cases would make the general use of this antiseptic inadvisable. As to effectiveness, if it is effective, it presumably acts as an antibacterial agent, and that should be most evident in primary infections. The recovery of 80 per cent of patients with impetigo in one week is good but hardly better than one would expect in a number of other agents. The authors lay particular stress on the good results obtained in infectious eczematoid dermatitis and various ulcers, but in these conditions the underlying cause, the concomitant treatment with dressings, rest or other measures play so large a role that it is difficult to tell how much applied antiseptic had to do with the results. If benefits in these ulcers were due to antiseptic action, one would have expected them to be more evident in primary infections. There is another possibility that the effect of this drug on gram-negative organisms is important, but it must be remembered that the pathogenicity of the gram-negative strains is not known. At least in treating secondary infections in dermatophytosis we found that if one controlled the staphylococci and streptococci with penicillin the gram-negative organisms, even Ps. aeruginosa, would disappear. It is evident that this nitrofuran is good, but how good? I should like to say something that is rather obvious, and I hope that it will be regarded as a criticism of myself and not of Dr. Downing. My associates and I recently tried to evaluate the topical value of penicillin in a hurry. Some opinion had to be given promptly, and we omitted controls. When we were all through we knew that penicillin was good, but we had no way of estimating how good. The clinical evaluation of any therapeutic measure is most difficult and time consuming. The addition of controls makes it more difficult and more time consuming, but without controls it is just hopeless. Occasionally one can treat one lesion with one procedure and another with another in the same patient. Occasionally we can tell something by using different measures in sequence, but as a rule one needs two parallel series of unselected cases, one treated by the drug under investigation and the other by some standard procedure. Otherwise, when the work is finished, there is no answer to the problem.

DR. FRANCIS W. LYNCH, St. Paul: The work of the authors and the experimental studies of others show that this drug has superior features. It is effective in high dilution, in the presence of organic materials and against many organisms, gram-negative as well as gram-positive. It does not interfere with healing tissues. It is incorporated in a highly satisfactory base. Unfortunately, there are deficiencies in our knowledge. No unbiased study of minimal bactericidal concentrations has yet been published, and it will be interesting to see the comparison with the other agents recommended by Meleney's group. Also, the role of Furacin as a sensitizer is still to be determined. Experience with the sulfonamide drugs and penicillin makes one suspicious that prolonged and repeated clinical use may lead to unfortunate experiences. Shipley reported that cutaneous irritation was observed in "only 2" of the first 100 patients, but this figure does not allow a conclusion that the drug may not cause considerable trouble. While my experience with the drug has been less extensive and critical than that of the authors, I am in general agreement with their conclusions. I used Furacin Soluble Dressing in 80 cases. The results in 8 cases of impetigo and 2 of ecthyma were as good as those with sulfathiazole or penicillin. In folliculitis I was more fortunate than Downing, but in sycosis I was disappointed. Incorporation in a more penetrating base may help in these diseases. In secondarily infected dermatitis the preparation was beneficial, but uncomplicated mycotic dermatitis, neurodermatitis and psoriasis were not helped. My experience in infectious eczematoid dermatitis was similar to that with other agents, but Furacin seems less likely to cause irritation or hypersensitivity than do sulfonamide drugs or penicillin. Perhaps past experience has taught the limitations and disadvantages of prolonged application of antiseptics in that peculiar disorder. The successful treatment of various types of ulcers and wounds is encouraging. I have found Furacin useful in dressing the slightly infected wounds after electrosurgery of warts and nevi. There and in all disorders I use it with less hesitation than sulfonamide compounds or penicillin, because the patient has so much less to lose if hypersensitivity occurs. I think that Furacin should prove to be a useful addition to the short list of antiseptics satisfactory in dermatology. Dermatologists must take more interest in scientific study of antiseptics, as neither bacteriologists nor surgeons are familiar with our problems. Downing reiterates Underwood's comments that topical agents must be tested, not only in the laboratory and on normal skin but also in the presence of dermatitis and particularly in allergic dermatoses. Dermatologists should search for agents which are not likely to be given internally and thus avoid the unfortunate results of systemic hypersensitization which developed in many patients as a result of unwise application of sulfonamide compounds and penicillin. While Furacin has some effect on systemic infection, it seems not likely to be used orally or by injection, and this seems to be its major advantage in topical therapy.

DR. W. R. HILL, Boston: In a patient who had been receiving treatment for acne a traumatic ulcer of the leg developed. An application of 5-nitro-2-furaldehyde semicarbazone was used on this lesion, and within a period of twleve hours a generalized psoriasiform eruption developed. Four days later the skin over the right scapula, which had been sensitized to adhesive tape several months prior to the present dermatitis, showed psoriasiform lesions outlining the site of the adhesive dermatitis. All local therapy was omitted, and within a week the entire psoriasiform eruption had disappeared. Specimens of skin removed for biopsy from several sites, including the area sensitized to adhesive tape, were consistent with the histologic picture observed in psoriasis resulting from arsenical sensitization.

Although reactions to patch tests performed one week after the application of 5-nitro-2-furaldehyde semicarbazone were negative, we thought that the drug was the most likely cause of the dermatitis.

Dr. John Godwin Downing, Boston: I wish to thank the discussers. I was pleased to know that Drs. Hopkins and Lynch would lead the discussion. I knew that their conservative evaluation of this drug would be extremely helpful. Throughout this study the manufacturer was cooperative and anxious to try to eliminate the factor causing the sensitivity by stabilizing the vehicle, which I believe is a factor. We retested some of the original formula and a new formula on 25 patients and then retested them after a period of ten days. These studies show that we have a drug with definite sensitizing properties for normal skins. In this report I have tried to make a conservative evaluation of this drug. An attempt has been made to indicate the entities in which it has been found to be of value, and to stress the untoward reactions caused by its use. By the latter we hope to avoid the pitfalls which have occurred in the use of known sensitizers, such as mercury, sulfonamide drugs and penicillin. All dermatologists are cognizant of these and warn patients accordingly when prescribing them. The sulfonamide compounds have been so notorious in producing sensitization reactions that most dermatologists avoid using them in the form of ointments. At the meeting of the American Dermatological Association in Virginia, sensitization from the topical application of penicillin was discussed and cited as being as frequent as 20 per cent. Two recent papers by Gottschalk and colleagues have shown that in 10.4 per cent of the patients treated with penicillin ointment a contact dermatitis developed. Later they showed that by means of patch tests they were able to produce epidermal sensitization to penicillin ointment in 4.5 per cent of 200 persons. They concluded that there is no contraindication to well controlled experimental use of penicillin locally, provided the patient is followed carefully and observed for untoward reactions. Perhaps we should hesitate to introduce a new antibiotic. However, if we read the literature, we will all suffer temerity in treatment, for the local action of even boric acid has been condemned. Practically all usable drugs have their contraindications. However, proper use of them and careful observation of the patient should prevent these reactions, with the exception of the rare case as an unforeseen idiosyncrasy such as the patient described by Dr. Hill. I do not recommend that Furacin Soluble Dressing be used on all ulcers and infections in which old and tried drugs have produced satisfactory results, but I do believe that it will produce results in the aforementioned entities resistant to ordinary therapy.

Toxoplasma.—Since its original description over thirty years ago, spontaneous infections with Toxoplasma have been reported in a large number of species of mammals, reptiles and birds from many parts of the world. In 1923 Jankû reported the first instance of human infection. The disease occurred in an infant as an encephalomyelitis with chorioretinitis. Jankû described the micro-organism but was unable to identify it. Subsequent morphologic studies have established the identity of Jankû's case and it is now accepted as the first reported case of human toxoplasmic infection. The second case of human infection with Toxoplasma was reported by Torres in 1927. The disease occurred in an infant and at that time the parasite was classified as an encephalitozoon, although Toxoplasma was considered. . . . Since the report of Wolf, Cowen and Paige 15 other cases of human infection with Toxoplasma having pathologic study have appeared in the literature, making a total of 18 cases to date. Thirteen have occurred in infants, 1 in a child 6 years of age and 4 in adults. In 4 instances Toxoplasma was recovered and identified biologically by inoculation of the diseased tissues into laboratory animals. The other 14 cases have had morphologic studies in which the organisms have been identified in tissue sections.—Callahan, William P., Jr.; Russell, William O., and Smith, Margaret: Human Toxoplasmosis, *Medicine*, December 1946.

RINGWORM OF THE SCALP

Report of the Present Epidemic

RICHARD J. STEVES, M.D.
Des Moines, Iowa
and
FRANCIS W. LYNCH, M.D.
St. Paul

In recent years ringworm of the scalp has assumed a position of considerable importance in the United States. It was formerly unnecessary for most physicians to be familiar with the problem because of the rarity of the epidemic form in this country, but recently epidemics have spread the disease widely throughout the nation. Some forms of ringworm of the scalp spread rapidly, are capable of causing epidemics and are resistant to topical therapy. Because of the increasing number of cases of this type the problem has become one of public health, and protection of the community is as important as treatment of the individual.

In 1822 Wilkinson [1] recorded an epidemic in England. Cases have since been reported throughout the world, but the greatest incidence of the disease has been in France and in England. In 1843 David Gruby [2] described the causative organism of epidemic ringworm and named it Microsporum audouini. His work went unnoted or disbelieved until 1910, when Sabouraud [3] "rediscovered" the Microsporum of Gruby and succeeded in growing it on artificial mediums. The discoveries of Sabouraud demonstrated that ringworm of the scalp can result from infection with either the Microsporum or the Trichophyton group of fungi.

TYPES OF INFECTION

Both the Trichophyton and the Microsporum group have species which are (*a*) pathogenic principally for certain lower animals (zoophilic) and (*b*) species which are pathogenic principally for human beings (anthropophilic).[4]

Infections contracted from animals have two important characteristics; they are but slightly, if at all, contagious among human beings, and they either are self limited or respond to topical therapy. Humans are poor hosts for this group of fungi, and, as Lewis and Hopper [5] showed, the self-limited features of these fungi may be accounted for by the development of antibodies and the production of an inflammatory reaction in the neighborhood of the infected hairs.

Kerion is a descriptive term denoting a fungous infection of a hairy region in which the inflammatory element is pronounced. There results a granuloma containing multiple openings from which pus exudes. The disease spontaneously disappears in two or three months. Kerion is usually caused by Trichophyton gypseum contracted from cattle and thus occurs most frequently in rural areas. In rare instances other fungi may produce an inflammatory reaction severe enough to be classed as kerion. Several cases were observed in our

present series in which kerion resulted from M. audouini.

In the United States, Microsporum lanosum is the important "animal" (zoophilic) representative of the Microsporum group and is generally transmitted by cats or dogs. Unlike the disease contracted from cattle, M. lanosum usually produces but slight inflammatory reaction. Several members of a family may be infected from the same pet, but extensive epidemics do not occur. Infections produced by M. lanosum must be differentiated from the epidemic form (M. audouini) because they are self limited and nonepidemic.

Infections with "human" (anthropophilic) fungi are grouped, because they are contagious and are usually resistant to topical therapy. The lack of antibodies and severe inflammatory reaction is ideal for survival of the fungus and allows infection to persist for years.

The genus Trichophyton has several species in the anthropophilic group, called endothrix because the spores invade the shaft of the hair. Infections with endothrix Trichophyton are rare and nonepidemic in the United States. Three cases which were observed by us accounted for 0.5 per cent of the total.

More attention will be given later to M. audouini, which has been responsible for the recent rapid increase in ringworm of the scalp in the United States.

DIAGNOSIS

Clinical inspection may suggest a diagnosis of ringworm of the scalp, and in some instances the causative species may be suspected. A gray patch containing broken hairs, a fine scale and a noninflammatory base suggests the epidemic form (M. audouini). In kerion, where the inflammatory reaction reaches its highest degree, the causative organism is usually T. gypseum, and cattle are the usual source of infection. However, infections caused by various fungi often resemble each other, and additional diagnostic procedures are necessary.

Microscopic examination of a hair covered with a 20 per cent solution of sodium hydroxide establishes the mycotic nature of the disease if spores are found, but this method usually fails to determine the genus of the species. If the spores are arranged in a sheath around the hair, the fungus is termed ectothrix (M. lanosum, M. audouini and T. gypseum); if the spores invade the shaft, the fungus is termed endothrix (Trichophyton of human origin).

The Wood light (black light) was first used in the diagnosis of ringworm of the scalp by Margarot and Devèze[6] in 1926. This light produces a brilliant green fluorescence of hairs infected by either M. audouini or M. lanosum but only a dull white or gray fluorescence of hairs infected by some of the endothrix Trichophyton fungi. The difference is striking and easily detected. Thus with the Wood light one can recognize infections caused by the genus Microsporum but cannot differentiate between those caused by M. lanosum (animal) and by M. audouini (human). It is of great value in the survey of school children because it permits early detection of cases. One or more negative examinations are usually required before a treated child is allowed to return to school.

A culture of the organism on artificial mediums (i. e., Sabouraud's dextrose peptone agar) is essential to the establishment of an etiologic diagnosis. Fluorescent hairs are placed on an agar slant and after seven days at room temperature the characteristics of the growth will enable an experienced observer to determine the genus and species.[7]

THE PRESENT EPIDEMIC

By "epidemic ringworm of the scalp" is meant that form caused by M. audouini. Prior to 1940 the greater part of the United States was free from this resistant and highly contagious disease. Reports of its greatest incidence came from England and France, and after the first world war several epidemics were reported in Germany.[8] In New York and Chicago sporadic cases and localized outbreaks occurred, but Lewis and others[9] stated that prior to 1943 there was no report in the American literature of a pandemic such as is now affecting children in widely separated parts of the country. According to Mitchell, Story and Macdonald,[10] an unusual incidence was observed in a school district in New York in November 1942. Epidemics also appeared in Philadelphia, Niagara Falls, N. Y., Chicago and Detroit[11] with thousands of cases in some cities.

In an attempt to determine the extent of the present epidemic questionnaires were sent in January 1946 to the health officer in at least two cities in each state and in each city with a population of over 40,000. Replies were received from 175 of 220 inquiries. Epidemic ringworm of the scalp had appeared in 61 cities (shown in fig. 1), and replies indicated that it probably was present in 27 additional cities. The limitations of such a survey are obvious, but it demonstrates the nationwide character of the present epidemic.

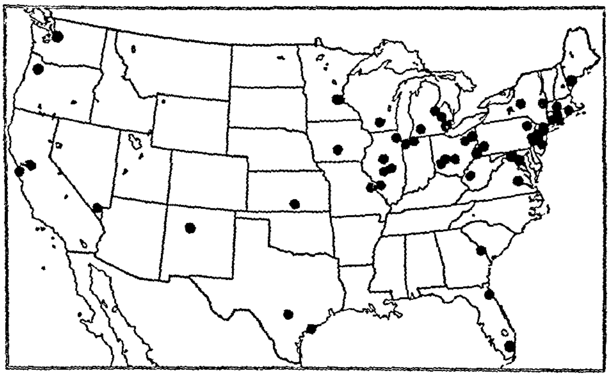

Fig. 1.—This map shows the location of cities in the United States in which the epidemic form of ringworm of the scalp has appeared. (The survey was made in January 1946.)

An unusual opportunity presented itself to study an epidemic in the twin cities of Minneapolis and St. Paul, where every form of ringworm of the scalp was rare prior to 1943. In 1945 and 1946 about 747 cases were observed in Minneapolis, St. Paul and surrounding communities. M. audouini was the organism responsible for all the cases in St. Paul and surrounding communities, but not in Minneapolis, where nearly 20 per cent of the cases were caused by other types of fungi (see the accompanying table).

Practically all patients presented one or more areas of broken hair and gray scaling with little other evidence of inflammation. Both clinically and in their fluorescence, definite similarity existed between cases caused by M. audouini and those due to M. lanosum. The occiput was the usual site of initial involvement, although it often began in the temporal region and occasionally elsewhere. Infection of the eyelashes was noted in 1 case from which M. audouini was isolated.

Of 635 children infected by M. audouini, the average age was 7.2 years, the ages varying from 1 to 16 years.

Infection was found nine times as often in boys as in girls.

The epidemic apparently began in St. Paul with the infection of a Negro family, and 3 per cent of the total cases were observed among Negroes. This is approximately 50 per cent greater than the proportion of Negro persons in the total population.

In St. Paul several examples of ringworm of the scalp were recognized in 1941, a few more in 1942 and 1943, and the number slowly increased through 1944. The rapidity with which the disease spread during the year 1945, when, for a time in St. Paul, the epidemic threatened to become out of control, is indicated by figures 2 and 3 and by the following figures:

Total Cases to Date	Minneapolis	St. Paul
Jan. 1, 1945	2	51
Jan. 1, 1946	51	584

TABLE 1.—*Causative Organisms in 1945 and 1946 Epidemic*

	Minneapolis Cases	St. Paul Cases	Total Cases
M. audouini	51 (81%)	584 (100%)	635 (98%)
T. violaceum	2 (3%)		2 (0.3%)
M. lanosum	9 (14%)		9 (1.5%)
T. crateriforme	1 (2%)		1 (0.2%)

TABLE 2.—*Analysis of Treatment of 486 Cases*

	Cases	Cures	Failures
Manual treatment	298	75 (25%)	225 (75%)
X-ray epilation	188	150 (80%)	38 (20%)

During the epidemic in St. Paul and Minneapolis cases were observed in surrounding communities. Sporadic cases occurred in two suburbs and mild epidemics in three. Several small cities 35 to 150 miles distant had a total of about 100 cases. It appears that the epidemic in Minneapolis and St. Paul acted as a focus for dissemination to surrounding smaller communities.

TREATMENT

Spontaneous cures in children with ringworm of the scalp were noted by Sabouraud;[12] Lewis and his associates[13] emphasized that the disease is self limited or responds to topical therapy when caused by organisms pathologic for lower animals. In the present series all cases caused by M. lanosum were cured within two months. The epidemic form (M. audouini) is notoriously resistant to therapy, though it disappears spontaneously at puberty. Livingood and Pillsbury[11] reported cures by means of topical applications in one third of the cases studied.

The results of treatment were carefully reviewed in 486 cases in St. Paul (table 2). In each case the scalp of the child was clipped and fluorescent hairs were manually removed once or twice a week. The parents were instructed in the daily application of simple topical remedies (mild tincture of iodine, or ointments containing sulfur, ammoniated mercury or undecylenic acid and its zinc salt). Within three months 25 per cent of 298 patients were cured. In 188 cases the children were treated with epilation by means of roentgen rays in addition to the above regimen, and 80 per cent were cured within three months. (To some extent the group which did not receive roentgenologic epilation was selected because of a minimal infection, but the group also included patients who refused epilation or for whom this procedure was temporarily unavailable.) Patients were regarded as cured after two examinations under the Wood light failed to show fluorescent hair. The sex or age of patients had little influence on the response to treatment.

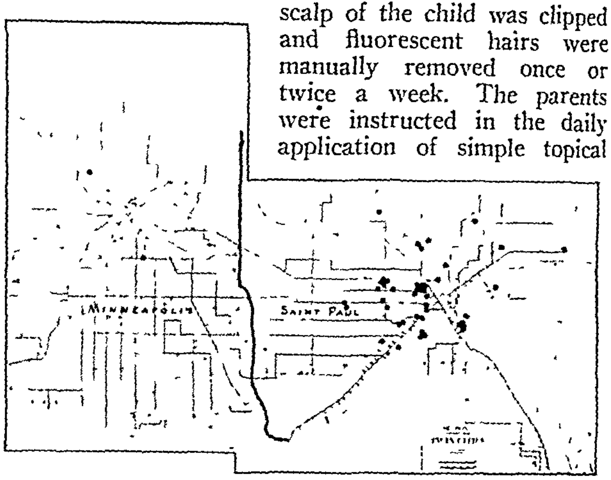

Fig. 2.—Each dot locates the residence of 1 child with ringworm of the scalp in Minneapolis and St. Paul, reported prior to Jan. 1, 1945.

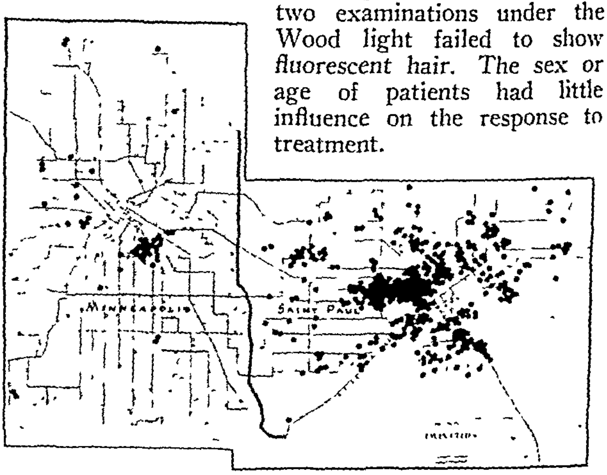

Fig. 3.—Each dot locates the residence of 1 child with ringworm of the scalp in Minneapolis and St. Paul, reported prior to Jan. 1, 1946. Comparison with the map in figure 2 demonstrates the rapid spread of the epidemic during 1945.

EPIDEMIOLOGY

It is unique in medical science to have the spread of a highly contagious disease depend on the transfer of infected hair from one child to another. Contact occurring within the school has been considered important, but we believe that the school itself is not a major

12. Sabouraud,[3] p. 214.

13. Lewis, G. M., and Miller, H. C.: Ringworm of the Scalp, Arch. Dermat. & Syph. 29: 890 (June) 1934. Lewis, G. M.: Ringworm of the Scalp: Curability Without Depilating Measures, Am. J. M. Sc. 189: 364 (March) 1935. Lewis, G. M., and Hopper, M. E.: Ringworm of the Scalp, Arch. Dermat. & Syph. 35: 460 (March) 1937.

factor in an epidemic. The incidence of new cases was as great during the summer months as during the school year, although many were unrecognized until the children returned to school. Of the seventeen schools involved in Minneapolis, epidemics occurred in two. In St. Paul ringworm appeared in fifty-three schools, but in thirty of these there were fewer than 5 cases each.

The frequent occurrence of the disease in siblings demonstrated its contagiousness by means of intimate contact. Among the preschool group 43 per cent had siblings with the disease; in one family 6 of 9 children were infected.

Numerous observers have suggested the barbershop as a source of new infections. Evidence here is entirely circumstantial and is based on the observation that the disease occurs most frequently in boys (9:1 in our series) and that the usual site of onset is the occipital region. It is contended that the clippers and the neck brush would carry infected hairs to the occipital region and would also explain the increased incidence in boys. No case came under our observation in which the infection could with certainty be traced to a barbershop. Although 80 per cent of the boys patronized public barbershops, none of the girls did so.

The deposit of infected hairs on the backs of theater seats has been suggested as a means of spreading ringworm of the scalp. Reif [11] believed that this was important in the spread of an epidemic in Niagara Falls, N. Y. Farley [14] found that after four hundred and twenty-four days hairs infected with fungi produced a growth on cultural mediums. Evidence is available that theater seats may be grossly contaminated with infected hairs. Theaters were attended by 97 per cent of 114 children with ringworm of the scalp who were questioned by us, and 78 per cent of this group admitted attending theaters after they knew they had ringworm. In our opinion contamination of theaters was probably an important factor in the development of the epidemic in Minnesota.

The greatest incidence of the disease occurs in the East and Middle West (fig. 1). This may be due to New York City, Washington, D. C., Chicago and Detroit acting as large foci from which other communities are infected. As shown by this study, other cities in which the epidemics are less extensive may act as secondary foci, producing dissemination to still smaller communities.

COMMENT

The experience of the past few years in Minnesota has demonstrated that it is important for all physicians to be familiar with the epidemic form of ringworm of the scalp. In many localities it is occurring for the first time and must be differentiated from the forms of ringworm which previously existed in those areas.

It was interesting to observe and compare the epidemics in the adjoining cities of Minneapolis and St. Paul. In St. Paul the epidemic was severe and early in 1945 threatened to become out of control, whereas in Minneapolis the number of cases was relatively few. We believe that the reason for these differences is principally in the amount of effort which was expended in combating the epidemics during their early stages. St. Paul was one year ahead of Minneapolis in experiencing serious numbers of cases. Thus facilities were in readiness in Minneapolis, and there was no delay in giving patients roentgen ray therapy once the diagnosis was made.

The methods of control which should be employed to prevent an epidemic have been excellently presented by Lewis and others.[9] If the active cases in any given locality exceeds a certain number, the diagnostic and therapeutic facilities will be unable to cope with the situation, and the epidemic can be brought under control only with great difficulty. This has occurred in several cities in the United States, and the disease rages unchecked, with the number of cases ranging in the thousands. In St. Paul the epidemic was controlled only with great difficulty and at a considerable cost. In other cities in Minnesota early recognition of the disease and adequate facilities for treatment brought the epidemics quickly under control.

Because of the national scope of the present epidemic we think it important for physicians to raise their threshold of suspicion in diseases of the scalp. Any gray, scaling patch containing broken hairs should be suspected of being ringworm, and physicians should request aid in obtaining an exact diagnosis. In the threat or in the presence of an epidemic the individual physician cannot handle the problem alone. The public health aspects of the disease far outweigh the treatment of the individual patient, and it is the duty of the school, city, county and state health departments to take adequate and early precautions to prevent spread. In Minnesota special ringworm centers were established for the diagnosis and treatment of the epidemic, and in St. Paul a special school was instituted for the children who were prohibited from attending regular schools.

Use of the Wood light is indispensable in the presence of an epidemic. It is used in surveying schools to detect early or unrecognized cases, and it is the only satisfactory method of determining when a case has been cured.

Patients infected with fungi pathogenic for lower animals may be cured with topical applications, and many patients infected with the epidemic form of the disease may be cured by topical application and frequently repeated manual removal of fluorescent hairs. In our experience, roentgenologic epilation was far superior both in rapidity and in percentage of cases cured and should thus be used routinely in the presence of an epidemic until better therapeutic methods are developed. New therapeutic agents are being studied and may prove highly effective.

SUMMARY

1. Information from questionnaires indicates that an epidemic form of ringworm of the scalp has appeared in most sections of the United States.

2. In many communities, including Minnesota, this disease is appearing for the first time.

3. A recent epidemic occurring in Minnesota has involved 747 children.

4. In a selected series of cases, 25 per cent of the children were cured by means of "manual therapy." Roentgen ray epilation of the hair of the scalp was followed by cure in 80 per cent of the cases, and this was the method of choice.

5. The spread from Minneapolis and St. Paul to smaller communities throughout the state is reported, and the possibility of an epidemic becoming out of control is stressed.

ADDENDUM.—The total number of cases of ringworm of the scalp in the epidemic in St. Paul reached 834 on Dec. 31, 1946, of which number only 3 were caused by Microsporum lanosum. On that date only 73 patients remained under treatment.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association and Hygeia, the Health Magazine
Chicago

(Continued from page 243)

(NOTE.—*Following is the thirteenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 13. *The Journal Gains*

1885

Almost forty years had passed since the American Medical Association had been organized at Philadelphia. In the intervening period the Johns Hopkins University had been founded; bacteria had been grown on artificial mediums; Alexander Graham Bell had introduced the telephone, for which many doctors' wives would curse him roundly in the years that were to come.

The gonococcus was discovered by Neisser in 1879, and Pasteur isolated the streptococcus and the staphylococcus in 1880. Every one of these discoveries was to be reflected within a few years in the discussions of the scientific sections of the American Medical Association.

Dr. John Shaw Billings had taken a considerable part in the work of the American Medical Association, particularly in its Section on State Medicine (which we today would call public health). In 1880 John Shaw Billings published the first volume of the *Index Catalogue,* the first attempt to index regularly the medical periodical literature of the world.

In 1880 also the American Surgical Association was founded, the first society devoted exclusively to specialists. Only a few years before there had been many discussions on the rights of specialists compared with the rights of general practitioners. The economic, scientific and social aspects of specialization in medicine were to attract increasing attention and to become major subjects of medical discussion as the years rolled by.

With the discovery of bacteria and of first antiseptic and then aseptic surgery the surgeons began increasingly to invade portions of the body never before accessible. In 1881 Billroth resected the pylorus, and in the same year Czerny described vaginal excision of uterine tumors and Hahn removed a kidney. In 1882 Robert Koch discovered the tubercle bacillus.

The scientific papers read before the sections of the American Medical Association began increasingly to attempt to reconcile the newer knowledge of germs in the causation of disease with the weird and sometimes mystical classifications of disease that had characterized previous excursions by the medical profession into the problems of disease causation.

THE NEW ORLEANS SESSION

As 1885 dawned THE JOURNAL for January 3 of that year apologized because the last issue for December of 1884 had appeared late. A single galley of proof had been tied up somewhere in the Christmas rush in the postoffice, and the list of members had taken two pages more than had been anticipated because of the increase in membership.

There was still some argument as to whether or not diphtheria was a contagious disease. Indeed, in the light of *post hoc* knowledge, some of the discussions of the 1880's seem bizarre indeed. There was quite a battle over the question of whether or not a solid stethoscope would convey sound better than a hollow one.

THE JOURNAL was beginning to make its presence felt on the medical profession. The interest in the American Medical Association was increasing. Sectionalism was developing in American medicine; it was to be the source of much anguish and misunderstanding for years to come. These misunderstandings reflected in some instances the thirst for prestige and power by the publishers and editors of some of the Eastern medical journals.

Another source of disturbance was the practice of the homeopathic system and the bitterness against homeopathy manifested by such leaders as Oliver Wendell Holmes. The powers in the American Medical Association felt that the abandonment by the New York State Medical Association of principles of ethics concerned chiefly with consultations by members of the Association with physicians who adhered to peculiar medical beliefs was a direct thrust at the foundation stones of the Association itself.

THE JOURNAL

In March 1885 N. S. Davis gave account of his progress with THE JOURNAL. He informed the readers that he had told the Board of Trustees that "under no circumstances" would he extend his work as editor beyond the current year. Less than two years had passed since the first number of THE JOURNAL was issued. There had been continuous growth of the membership, which had increased from 1,428 in 1875 to 3,887 in 1885. The *British Medical Journal,* cited everywhere as the foremost publication in medicine, had been founded in 1865 and had achieved by 1885 a circulation of 12,000.

In a later editorial the editor noted how greatly THE JOURNAL had aided in hastening the publication of important contributions made at the annual session and how well it had reflected the general progress of medicine in the United States. The annual income of the American Medical Association had risen from $5,008 in 1879 to $13,017.25 in 1884 and to $18,117.25 in 1885. The Association was thus quite solvent: its income just about balanced its budget. We see later that this balancing was made possible by the failure of the editor and of some of his helpers to collect any income whatever for their work. In a final editorial on the current situation, Dr. N. S. Davis pointed out that he had been unable to employ necessary help because of inadequate funds in the treasury and that the printer had been willing to postpone some of the payment on his account. "By deferring all pay for his own services, and limiting thus the number of paid assistants, he conserved enough in the treasury to pay all publication expenses promptly and at the end of the year from the later collections received for himself a reasonable remuneration for the editorial work performed and left a surplus sufficient to pay the other current expenses of the Association."

The editor had been disturbed by the fact that members who had contributed papers, reports and addresses had failed to send them promptly to The Journal in accordance with the By-Laws. Other medical periodicals had had access to this material and they had taken away its journalistic newness by publication of abstracts before there was opportunity to publish the material in The Journal. Dr. N. S. Davis then established the policy that the address of the President of the American Medical Association should be published in the week in which he delivered it and the chairman of the individual sections would have their addresses published in The Journal each week that followed.

In the first editorial for April 1885 the editor discussed at considerable length the problems of printing involved in publishing The Journal. There were attempts to turn over the publication to commercial publishers and thus to take it away from its direct control by the Board of Trustees. Dr. Davis felt that it was time to fix the place of publication for a term of years and to purchase necessary printing equipment so that the composition of The Journal would be the work of the Association, although the press work could be done elsewhere. Dr. Davis urged the establishment of its own press by the Association because he felt certain that this would lead eventually to a much better publication and to complete control by the organization itself.

Another sign of growing pains was the introduction of several resolutions having to do with the membership in the Association and with membership on the nominating committee. There was naturally some objection to having members of the nominating committee nominate themselves to important offices.

The meeting in 1885 at New Orleans heard an address by the President, Dr. Henry F. Campbell of Augusta, Ga. Southern oratory rolled in resounding phrases. Thus he spoke of the passing of S. D. Gross and J. Marion Sims:

> With shining robes more honorable than any toga of office we can put upon them, with crowns more resplendent than those of earthly monarchs, and with harps and melodies more entrancing than the music of our love or the anthems of our praise, they hear no more the voice of human adulation.

However, after some pages of this fluorescent diction Dr. Campbell turned his attention to serious criticism. He praised the development of The Journal. He poured satire on professional testimony in the courts and on the lawyers who cross examined the medical witnesses. He urged the establishment of a section devoted to forensic medicine.

THE ARMY LIBRARY

Dr. John Shaw Billings reported the complete success of the effort to obtain an appropriation from Congress for fireproof buildings for the Army Medical Museum and Library, and he announced that the building operations would soon be commenced. The building, reported first in 1885, still stands in Washington in 1947—a veritable firetrap—holding in its bursting walls millions of books and pamphlets of incalculable value while members of the medical profession and of innumerable other agencies urge the Congress again and again to make adequate appropriation for the building of a modern structure worthy to house the treasures whose existence is threatened every moment by the inadequacy of the old building that now contains them.

THE EDITOR

The Board of Trustees announced that it had earnestly requested Dr. Davis to withdraw his resignation and to continue his relations with The Journal as its supervising editor. His sense of duty impelled him to suspend his resignation and to yield to the unanimous request of the Board to continue his editorial superintendence of The Journal until such time as a successor could be appointed.

THE BENJAMIN RUSH MONUMENT

The House of Delegates had been intent on developing funds for the monument for Benjamin Rush to be unveiled at the meeting of the International Medical Congress which would be held in 1887. Some $45,000 was needed for this purpose and it was to be collected by a maximum contribution of $1 from each subscriber; the monument would be erected in Washington. The committee called attention to the manner in which statesmen, military heroes and naval heroes had been honored with monuments as had also painters, sculptors and various scientists.

Benjamin Rush received his A.B. degree from Princeton when less than 15 years old. He studied medicine with John Redman in Philadelphia for six years and translated the aphorisms of Hippocrates from the original Greek. As a student when only 17 he had described the epidemic of yellow fever that prevailed in Philadelphia. After obtaining his degree of doctor of medicine at Edinburgh in 1766 he studied in London and in Paris and returned to the United States in 1769. He was one of the signers of the Declaration of Independence. Benjamin Rush was one of the surgeon generals in the Army of the Revolution and a member of the convention that adopted the federal Constitution, which he called "a masterpiece of human wisdom."

In 1789 he succeeded Dr. Morgan in the chair of theory and practice of medicine in the Medical College of Philadelphia. Once the federal government was established, he devoted himself wholly to his profession and to civic affairs. The only office which he accepted as a reward for his many government services was the position of president of the mint, which he held for fourteen years. He was one of the vice presidents of the American Philosophical Society; he aided in founding Dickinson College; he was president of the American Society for the Abolition of Slavery. Benjamin Rush died in 1813 at the age of 68 as a victim of an epidemic of typhus.

1886

ST. LOUIS

Early in 1886 attention was called by THE JOURNAL to the crowded character of the program of the American Medical Association. The difficulty was that the addresses of the chairmen of the sections were taking too long in some instances and not long enough in others. This agitation was to culminate in the eventual divorcement of the reading of the chairmen's addresses from the general meeting and the limitation of such addresses to the sections themselves. This divorcement, however, was another step in the tendency toward specialization, since its inevitable result was to limit the consideration of special topics to the specialists and to make impossible their delivery to the general practitioners, who might be said to need them most.

There was also some criticism of the attempts to build a program by the voluntary offering of papers. The chairmen and secretaries were urged to invite contributions from competent authorities on important subjects so that there would be at least one or two leading papers in each section and at least one or two equally qualified members to open the discussions of the papers.

One cannot but pause to marvel again at the insight and organizational ability of Nathan Smith Davis. As one views the progress and development of the American Medical Association and the elements in its activities which have obtained permanent status, one finds again and again that the concept arose in the mind of Dr. N. S. Davis, that it was presented by him so clearly and succinctly as to carry conviction and that he fought for these steps in progress with a persistence and sincerity that led inevitably to their success.

BATTLE OVER THE INTERNATIONAL CONGRESS

The jealousies of which mention has been previously made flared into public view early in 1886, when the editors of some of the Eastern medical journals denied the right of the American Medical Association to participate largely in the formation of a forthcoming International Congress of Medicine to be held in Washington. These Eastern editors endeavored to sabotage the American Medical Association's committee and tried to deter members of the profession from accepting any official positions in the preliminary organization of the congress. In an attempt to overcome this opposition, places on the national committee were offered to the most eminent of those in the opposition. The battle waged so fiercely that attempts were made to control the election of delegates to the meeting of the American Medical Association with a view to mustering a majority at the meeting in St. Louis. These efforts also failed.

Mingled with this controversy was the question of the status of the homeopathists. Apparently foreign countries had admitted homeopathists to their delegations and it was desired that homeopathists be admitted to the American delegation. Then arose the question of admitting not only homeopathists but also eclectics, physiomedical graduates, hygiotherapeutic graduates and those of some other schools. To settle the difficulty, an official announcement by the American Medical Association made it clear that any legally acknowledged practitioner would be admitted to the congress.

Much of the attack centered on Dr. John Shaw Billings, as secretary of the original committee of seven which was planning the congress. The American Medical Association called on him to explain exactly what he and his committee really did expect of the Association. The original committee of seven had been commissioned to go to Copenhagen in 1884 and to invite the International Medical Congress to meet in the United States. A somewhat satirical comment in THE JOURNAL stated that "they satisfactorily performed this office and through their spokesman promised the members a generous welcome, he pledging himself to do a variety of things without reservation (expressed, at least), as to the contingency of his not being allowed to have everything his own way."

Apparently there were a good many political appointments made to positions of distinction, and there was general resentment against these actions and attitudes.

MEDICAL ORGANIZATION

In the meantime there began to be repercussions in Philadelphia over the charge of political manipulation of its delegation to the American Medical Association. A secret caucus had been held for the nomination of delegates, and the members, having discovered this fact, began to be resentful. Some of these discussions led the editor of THE JOURNAL, Dr. N. S. Davis, to publish an editorial in the issue of Feb. 27, 1886 urging the possibility of reorganization of the American Medical Association along the lines of the British Medical Association with the fundamental principle of membership in a county and state medical society as a basis for membership in the American Medical Association. The decision to organize the American Medical Association along such lines had caused the organization of state medical societies where none existed and had caused the reorganization of state medical societies which had been allowed to die. The editor pointed out that the admission of two delegates from the faculty of each medical college and one from the staff of each hospital, lunatic asylum and dispensary not only gave these medical men a much larger number of delegates but removed from them the incentive to become members and to officiate as members in their own state medical societies. Ultimately this change in the method of organization was to be one of the most important single influences in building a strong democratic representative body.

This editorial led to an extensive correspondence objecting to the organization of the American Medical Association with branch societies as is done in Great Britain and insisting that the system whereby the state medical societies constitute the real branches of the organization was a proper one for a country such as ours. The organizational technic of N. S. Davis is nowhere better manifested than in this practice of writing an editorial to stimulate discussion in the correspondence columns, reactivating discussion by further editorials when it tended to die and thus maintaining the interest of members of the Association everywhere in the problems of its conduct.

As might be expected, however, there were certain definitely disorganizing influences which arose from this discussion. One finds an attack on a former President of the American Medical Association as being a man who did not merit the position but who was elected to it only for his political influence. There was an editorial in the *Nashville Journal of Medicine and Surgery* in February 1886 which was reprinted in the *Medical News* of Philadelphia, claiming that the American Medical Association was a body merely medicopolitical, full of political intrigue and trickery. There was an attack on this editorial accusing the editor of the *Nashville Journal of Medicine and Surgery* of having "the effrontery to parade such intentions before an intelligent profession." The political battle being waged in editorials and in correspondence was moving into the stage of hand-to-hand conflict at the next annual session of the American Medical Association.

SOCIAL FUNCTIONS

In April 1886 Dr. Davis was again moved to turn his attention to the social functions at the annual session. He expressed his appreciation of the meeting in Boston in 1849, when "one evening was set apart for a general social mêlée or promenade in a public hall for the laudable purpose of affording more direct social intercourse of members from all parts of the country. With genuine good taste the local committee provided no other refreshments than coffee, simple cakes and fruit on a side table where those who wished could partake when they pleased. But this simple and very pleasant example was quickly converted into the form of a public banquet, which each subsequent local committee of arrangements endeavored to make more magnificent and costly than their predecessors, until at New York in 1853 the banquet alone was said to have cost more than $10,000; and the next year at St. Louis its extravagance and the excesses accompanying it led to the adoption of a resolution offered by the late Professor S. D. Gross forbidding all subsequent committees of arrangements to provide any public banquet in connection with the annual meetings of the Association."

This multiplication of official functions and similar jamborees led eventually to the adoption of a general rule that each alternate meeting should be held in Washington and that the necessary expenses for halls and programs should be met by the Association.

THE ST. LOUIS SESSION

When the Association convened in St. Louis it was announced that protests had been entered against the delegates from the Philadelphia County Medical Society, the New York Academy of Medicine, the Tri-State Medical Society, the Mississippi Valley Association and the Davidson County Medical Society, and one Tennessee doctor protested against the Tennessee State Medical Association.

The meeting in St. Louis brought an attendance of 1,100. The address of the President, Dr. William Brodie, paid tribute to the great men of the profession who had died during the year, among whom was Dr. Austin Flint. Dr. Brodie told of the effectiveness of the Association in raising the standards of medical education. He listed the prize essays as an indication of its scientific contribution. He noted the organization of special societies, of ophthalmologists, otologists, gynecologists, dermatologists, public health officers, laryngologists, surgeons and pathologists. Thus the rise of specialization had been exceedingly rapid. It was Dr. Brodie's opinion that nothing could be gained by changing the nature of the American Medical Association to resemble that of the British Medical Association with its branches. He forecast a feeble reception for the report of the committee of the ninth International Medical Congress and he pleaded with those who had fought the committee to give it their full support.

Apparently the spade work preliminary to the convention had been well done. The report of the committee was, on motion, received and adopted with enthusiasm and without an audible negative vote by the entire convention with almost a thousand delegates in the hall. Indeed the editor of The Journal was delighted to report complete harmony, whereas two months previously every one seemed to be sharpening his knife in readiness for the conflict.

The committee on organization of the International Medical Congress in 1887 made its report suggesting the name of N. S. Davis of Chicago for president and John B. Hamilton of Washington, D. C., as secretary general. The vote was recorded as unanimous. A motion offered by a Pennsylvania delegate to reconsider this motion was laid on the table.

At this session of the Association an amendment was adopted that each section should nominate its own officers. The establishment of a section on dermatology and syphilis was approved.

The business committee, acting as a reference committee, endorsed the views of the President that all papers read in the annual session should become the exclusive property of The Journal; it asked the Judicial Council to take action against members who introduced proprietary remedies and appliances. It recommended the appointment of a committee to study reorganization of the Association. A resolution was adopted that the Association approve cremation or incineration of the dead as a sanitary necessity in all populous cities.

The meeting was notable for the presence of General William Tecumseh Sherman, who entered the room and sat on the platform during the fourth day of the session.

The Trustees reported on The Journal and then asked Dr. N. S. Davis to make an individual report. Dr. Davis expressed his dissatisfaction with the income from advertising and some defection in subscribers. These included, first, those disaffected by the New York New Code party and later the opponents to the organization for the International Medical Congress. Notwithstanding these defections there had been a total increase in members and subscribers. Dr. Davis had consented to remain as editor, and the Trustees expressed their confidence that the experiment in publishing The Journal was fully warranted and that some day it would prove that their experiment was sound.

The difficulties over delegates in this convention were thoroughly analyzed by the Judicial Council, which made its report on the final day of the session. The delegates from tristate societies were considered not entitled to admission, since the Association recognized only the state societies and the county, district and local societies affiliated with the state societies. It asked the Davidson County Medical Society in Tennessee to show up next time with some credentials which would prove its connection with the Tennessee State Medical Society. The evidence against the Mississippi Valley State Medical Society was found insufficient for consideration. The Judicial Council found also that the delegates from the Philadelphia County Medical Society had been elected by methods which were of such an irregular character that the delegates would have to be rejected. The Judicial Council authorized the return of the dues of these delegates.

When the meeting was over and the delegates had returned home, the *Medical Record* of New York published some editorial comments calculated to create the impression that this meeting of the American Medical Association was not really representative and that the action of the Judicial Council relative to the delegates from Philadelphia had started a serious split in the American Medical Association. To this the *Philadelphia Medical and Surgical Reporter* replied "It is hardly fair to speak of a split when only a few fibers are carried away; it would be more correct to say a shave or a scrape. The main body of the American Medical Association is today more united than it ever was, and it has lost the allegiance only of those who 'got mad' because they could not control." The editorial in The Journal of the American Medical Association proves that the attendance was most representative and that there was little danger that a proposed congress of American specialists "constructed from a union of half a dozen American specialist organizations could take the place of the Association."

1887

CHICAGO

In January 1887 the students of the Chicago Medical College presented N. S. Davis, in honor of his fifty years in medical practice, with an armchair and a revolving bookshelf. Such a piece of furniture as the revolving bookshelf is still found in one of the offices of the headquarters of the American Medical Association and is probably the very one which was presented to N. S. Davis at that time. In the history of medicine such gifts represent one of the finest amenities in medical relationships. In the same year Dr. J. Adams Allen, commonly known as "Uncle Allen," was presented by the students of Rush Medical College with a "tripod" consisting of a fat, chubby hand, made of solid gold. It was set on an onyx pedestal on which was inscribed:

UNCLE ALLEN'S TRIPOD

Remember these three
When we practice the art:
The condition of blood,
The nerves, and the heart.

This quotation was a verse of the college song at Rush based on some of Dr. Allen's sayings. The hand was in the position that he usually held when addressing the students.

The editorials in The Journal were increasingly devoted to scientific subjects, with less attention to problems of organization and representation. Dr. Davis was disturbed by the unsatisfactory reporting of the discussions in the sections, urging the reporters to give in greater detail the statements made by those who discussed the individual papers.

A SPECIAL ISSUE OF THE JOURNAL

As the time approached for the annual session, The Journal issued a special number in an extra large edition giving the program of the meeting and full information as to its various features. Members of the Association were requested to visit the publication office to see how well The Journal was getting along, and the members were promised four more pages of reading matter with each issue during the coming year.

As the time neared for the meeting of the Association, the members were again reminded that the business office at 65 Randolph Street was open at all times and that a clerk would be present at all times to welcome them. The Journal printing office was at 68 Wabash Avenue, only one square from the Central Music Hall, where the Association was to meet and where extra volumes of the Transactions published prior to 1883 were to be found for sale.

The President of the Association, Dr. Elisha H. Gregory, read an address on "Cell Antagonism" which differed from every previous address in being a highly technical review of knowledge of the cell. He concluded his address by calling attention to the near approach of the International Medical Congress and by requesting all members of the American Medical Association to participate and entertain properly the numerous delegates from abroad.

The Board of Trustees reported that The Journal had been well published with the operation of its own press and that Dr. N. S. Davis had consented to continue its management. The Association now owned several fonts of type. There seemed to be a small increase in its subscription, but this was due to the fact that 524 subscribers had been added while 244 had been removed for nonpayment and for other reasons, including death.

Again attention was called by N. S. Davis to the fact that the Code controversy in New York and the battle over the International Congress had resulted in considerable damage to the Association's membership. However, these two revolts had spent their force and there had been recently increased applications for membership and renewals of subscriptions—more, in fact, than at any previous time since The Journal had been established. Dr. Davis urged again an expansion of The Journal printing office and he gave credit particularly to Dr. William G. Eggleston as assistant in editorial work and to Mr. J. Harrison White, who was both foreman and printing office and advertising manager.

CHANGES IN ORGANIZATION

Most important at this session of the Association was the report of the special committee on changes in the plan of organization and by-laws. The proposed amendments included changes in the technic of choosing members, the elimination of the nominating committee and the substitution of a general committee, the elimination of the committee on publication and the substitution of the Board of Trustees, the choice of chairmen in the individual sections by election in the sections and the new method for choosing those who were to give the annual addresses in the sections. The report of the committee was adopted. As an indication of the difference of opinion, however, a standing vote was taken on the adoption of this reorganization and the final vote was 274 for and 232 against. A roll call of the states established a committee on nominations with a representative from each state.

THE RUSH MONUMENT

An extensive report was presented by the Rush monument committee including a statement by its secretary and by its treasurer. The committee had made a very minor start on the total of $45,000 which it had started to collect. The total sum which had been sent to the treasurer was $389, and the committee had spent $143.08 on its expenses.

THE ANNUAL DINNER

As this session neared its end, several resolutions were offered which were again fundamental to the progress of the Association. One had to do with the holding of an annual dinner in which there were to be two kinds of tickets, one without wines or liquors and one with wines or liquors, so that any members of the Association could come to the dinner and not drink without feeling that he was paying for the liquor that was drunk by others. This resolution was adopted by a large majority.

THE FINANCIAL CONTROL

A resolution was offered appropriating an honorarium of $300 to the permanent secretary. To this Dr. Davis offered an amendment to the effect that the Board of Trustees be a standing committee on finance to which all propositions for the appropriation of money should be referred and reported on before final action on the same by the Association. This simple resolution, which arose out of a motion to pay a small honorarium to the permanent secretary, was probably more significant in the financial prosperity of the American Medical Association as it exists today than any other action taken up to that time.

1888

CINCINNATI

The first volume for the year 1888 indicates that THE JOURNAL was edited for the Association by N. S. Davis, assisted by William G. Eggleston and N. S. Davis Jr.

A NATIONAL DEPARTMENT OF HEALTH

Early in the year THE JOURNAL began to agitate for a national department of health, with particular reference to a national department for the control of adulteration of foods. This, it must be remembered, was 1888. The United States does not yet have a national department of health, although it has the U. S. Public Health Service. It required the action of Theodore Roosevelt and the publication of books by Samuel Hopkins Adams called "The Great American Fraud" and by Upton Sinclair called "The Jungle" to obtain a national law that would regulate the purity of foods and drugs.

THE GENERAL MEETING

Arrangements began to be made for the next meeting of the Association in which the addresses of the chairmen would be read before the sections rather than before the general assembly. However, arrangements were made for three important addresses before the entire assembly, forecasting the modern period with the general scientific meetings, in which three complete sessions are given over to general statements reflecting the advancement of medical science.

RIGHTS OF A DOCTOR IN HIS CLINIC

The editor of THE JOURNAL was also a little annoyed because medical reporters had begun attending clinics in hospitals and selling them to Eastern medical journals. Indeed, one reporter had annoyed the editor considerably by selling three of the editor's lectures in this manner without even allowing him to see the reports as first transcribed or to read the galley proofs. A Chicago judge gave a bench opinion to the effect that such activities were illegal and that redress could be had by resort to the courts for this piracy of medical literary material.

KNOWLEDGE OF DIPHTHERIA

An editorial in the issue for March 31, 1888 pointed out that a member of the Association disagreed with the editor, who had said that diphtheria was a preventable disease. He asked the editor to explain how he would go about preventing diphtheria. The editor, after some elusive discourse on the subject, said that "diphtheria, erysipelas, cholera, yellow fever and some other diseases evidently depend on specific infections developed outside the human being and capable of being introduced into it in connection with the air we inhale or the food and drink we take. Hence our formula for the prevention of diphtheria does not consist of drugs to be obtained at the apothecaries, but of an abundance of pure air, good water, wholesome food, clean soil, and a clear personality." In the light of modern use of antidiphtheria toxoid, this formula can be viewed only with praise for its sincerity. Just a few weeks passed until the editor had to write on the subject again. A member had suggested that probably isolation and disinfection should have been mentioned. Here the editor did a brilliant piece of open field running by pointing out that any family that was as clean as he had proposed would have nothing to isolate or disinfect. It was his idea that isolation and disinfection are performed only after infection has already occurred and that therefore they have little to do with the prevention of infection.

DRESS REFORM

About this time a prominent German professor became convinced that gallstones and tight lacing had a definite relationship. The editor of THE JOURNAL rather doubted that there was a true causal relationship but he was inclined to think that perhaps it was just frequent coincidence. He pointed out that the tight lacing goes on during the day and is loosened up at night. However, he felt that persistent tight lacing could cause a change in the configuration and that probably after all some cases of gallstones and perhaps also cancers of the gallbladder were due to tight lacing. Incidentally, a few pathologists had found the liver completely deformed by the tight stays of the corset of that day. It is not surprising then to find that Dr. Helen L. Betts of Boston read a paper before the Gynecological Society of Boston in December 1887 on the dress of woman and its relationship to the etiology and treatment of pelvic disease. Dr. Helen Betts was an advocate of dress reform. She wanted women to get rid of all the clinging garments with which their bodies were enveloped and she wanted them to get some exercise and outdoor life similar to that permitted to boys. She attributed congestion of the internal organs of women to their clothing and their habits. She cited a case from her own practice in which she felt that this was the primary trouble:

> The first, clearest indication seemed to remove the superincumbent pressure; so, as usual, I examined her mode of dress. You will be interested from a professional standpoint to know what this patient wore. I examined her at her home, so she had on simply her indoor garments. There were knit and muslin drawers, flannel and muslin underskirts, hoopskirt and

> bustle, then a muslin and a dress skirt, seven bands; fourteen thicknesses were buttoned closely about the corset, and, not long before, her physician, having noticed that she wore her garters about her legs, said he feared they would interfere with circulation and advised that she should put an elastic band about the waist and fasten the stockings to this! I asked if her clothes were not oppressive. She said she thought she wore very light clothing but had noticed at night a purple crease about the waist where the bands came about the corset and wondered if that could keep her from gaining strength. With all this weight and compression this poor woman was waiting to get well, wondering why she could not stand, that her limbs ached and prickled, and why she could not walk without getting so tired. Neither physician nor specialist had spoken of her mode of dress.

And Dr. Betts went further by pointing out that the men doctors simply did not know about these things because the men themselves had never submitted to that kind of clothing.

The meeting in Cincinnati heard an address by Dr. A. P. Y. Garnett which was a fine analysis of the medical education of the day, a brief review of the International Congress and an urge to participate in the building of the Rush monument.

The editor of The Journal told his readers that he would have the official minutes in the following week and he begged them to disregard the inaccurate, hasty and imperfect reports of the meeting that had been published by the contemporaries. The personal journalism which was characteristic of that day had invaded the field of medical journalism. Dr. Davis was much annoyed with the telegraphic reports from the convention in Cincinnati to the New York medical periodicals. He did not see the reason for all the hurry. "No one," he said, "can possibly object to an accurate report of the business meeting of the Association, but as the matter now is, it usually takes some months to correct the inaccuracies of one week's issue of some of our electric contemporaries. Inaccuracy is neither condoned nor corrected by telegraph wires, notwithstanding the marvelous therapeutic properties of electricity."

"PATENT" MEDICINE ADVERTISING

At this meeting there came a resolution from the Arkansas State Medical Society condemning the religious press of the nation for its continuous endorsement of "patent" medicines and the fact that the religious press published "serious homilies on prayer and praise side by side with cures for consumption, cancer, Bright's disease and other incurable ailments."

THE RUSH MEMORIAL

The committee on the Rush memorial reported that it knew that every doctor wanted to give a dollar but that the dollars had not been forthcoming and that they had not found out how to get them. The committee, which had started out to get $45,000, had got $392 the first year and $498 the second year but it had now had an expenditure since the last report of $34.73. Some of the state medical societies had made contributions—notably $500 from Pennsylvania—which had paid $100 on account, and $100 had been promised from Michigan but had not yet shown up in the treasury.

TOO MANY SOCIETIES

As the year ended there began to be agitation against the number and variety of medical societies. The difficulty seemed to lie in having too many special societies which were detracting from the national organization. These special societies were apparently not only taking away the harmony from the national organization but also interfering with pronouncements of policy. The *New Orleans Medical and Surgical Journal* of November 1888 said:

> What will be the final effect upon the American Medical Association of the various associations of so-called *specialists*—the American Surgical Association, the Association of American Physicians, the Gynecological Association and all the others? It will be a sad day for the profession of America when the time-honored A. M. A. ceases to be *the* medical institution of the country.

Dr. N. S. Davis charged that those who had taken part in one or more of these specialists organizations and who had actively promoted the combination of all these in the so-called Congress of American Physicians and Surgeons had been actuated by the desire that the latter should ultimately displace and supersede the American Medical Association. He felt that the leaders in the specialties had never been satisfied with the liberal organization of the American Medical Association. Some of them had tried to restrict the whole business and management of the Association to a council of limited number capable of self perpetuation instead of the representative plan based on the state and local societies. He attacked these specialists for devoting themselves to their special societies rather than giving the major portion of their attention to the sections of the American Medical Association. Too, he was certain that after all the sections of the American Medical Association would triumph because the specialists must depend for much of their patronage on personal contact with the general practitioners and he concluded:

> Instead of the circle of American associations of specialists, accommodating in the aggregate less than 500 of the 50,000 or 60,000 members of the regular medical profession of the United States, having any serious tendency to supersede the American Medical Association, it will only serve as a convenient and really useful place in which the small but respectable class of exclusionists can work and dine without personal contact with the sunburned and weatherbeaten general practitioners of the healing art.

In The Journal of the American Medical Association for Nov. 24, 1888, appears this significant notice:

> *EDITORIAL CHANGE*
>
> Having accomplished all that he had hoped or expected to accomplish when he accepted the editorship of The Journal of the American Medical Association in 1883, and feeling the necessity for diminishing his responsibilities and constant work, the Editor of The Journal tendered his resignation to the Board of Trustees in the latter part of June last, the same to take effect on the 31st day of December 1888. At a special meeting of the Board of Trustees held in Chicago Nov. 9 and 10, 1888 the resignation was accepted, and John B. Hamilton, M.D., Supervising Surgeon General of the Marine Hospital Service and late Secretary General of the ninth International Medical Congress, was chosen unanimously to fill the place. He will enter upon the discharge of his editorial duties Jan. 1, 1889. We trust he will have a long and prosperous editorial career.

Thus apparently ended the visible leadership of Nathan Smith Davis. But it was only apparent! A study of the minutes of the Association and of the Board of Trustees during the continuing years proved that, as long as there was in him spirit and life, N. S. Davis was wholly devoted to the American Medical Association and its progress.

1889

NEWPORT, R. I.

Prophetic indeed was a little note that appeared in the editorial column of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Jan. 12, 1889. It said:

> There are a little more than eighty thousand persons practicing medicine in the United States, of whom more than sixty thousand are regular practitioners. When one third of the regular profession are members of the American Medical Association we can have the strongest organization and the best medical journal in the world.

As the Association faced its hundredth anniversary in 1947, there were about 190,000 physicians in the United States, and of these about 130,000 were members of the American Medical Association. THE JOURNAL had reached more than 130,000 subscribers, a figure representing more circulation than the ten next weekly journals of medicine in the world combined.

In 1889 the British Medical Association was in excellent financial condition. It occurred to the editor of THE JOURNAL to make some comparisons and to point out that a technic like that by which the British Medical Association was organized would be of vital importance to promotion of THE JOURNAL. Yet from various places in the United States came a variety of suggestions, one urging frequent meetings in Washington and the beginning of the first agitation for moving the headquarters of the American Medical Association to that city. The suggestion has never quite died. Again and again it reappears in the various motions and promotions frequently supported by the belief that in some manner the location of the headquarters of the American Medical Association in Washington would result in a sort of influence on the legislative and executive leaders that cannot be secured by any less intimate contact.

THE EDITOR OF THE JOURNAL

It will be remembered that the Board of Trustees of the American Medical Association accepted the resignation of Dr. N. S. Davis at the end of 1888. Dr. John B. Hamilton was elected to succeed him. He served as editor only from January to February of 1889; then he resigned the position for reasons which he stated succinctly in an editorial published in the issue of February 9. At that time the committee on general management, which was the Board of Trustees, took over control of THE JOURNAL.

EDITORIAL NOTICE

> When the writer accepted the position of Editor of the Association JOURNAL, although the Marine Hospital Service bill was then pending, as it had been for the past ten years, he had no certainty of its passage, but, on January 4 it passed both houses of Congress and became a law, which by prohibiting any original appointments into the service except to the rank of Assistant Surgeon, has the effect of creating a life tenure in the office of Supervising Surgeon General. He therefore tendered his resignation as Editor to the Board of Trustees and it was kindly accepted by them to take effect on a day named by himself. His editorial connection with THE JOURNAL will therefore cease with the present number, and until further notice the "Committee on General Management" will take charge of the affairs of THE JOURNAL. With the most sincere thanks to those who have sent him kindly letters, his best wishes for the continued success of THE JOURNAL, and the renewed prosperity of the Association, the Editor assumes his life work in the Marine Hospital Service.
>
> JOHN B. HAMILTON.

John B. Hamilton was born in Jersey County, Ill. Dec. 1, 1847, the year in which the American Medical Association was founded. He graduated from Rush Medical College in 1869. Following his graduation he entered the Marine Hospital Service and rose rapidly to the rank of Supervising Surgeon General. His surgical skill won for him a position in Rush Medical College, where he became professor of the principles of surgery and clinical surgery. He obtained special recognition for his operations for hernia and for his skill in surgical diagnosis.

In "American Medical Biographies," edited by Howard A. Kelly and Walter L. Burrage, appears the statement that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION was never more successful than under his four years of editorship. His second term as editor began in 1893. This first period occupied just two months.

In 1889 Dr. Oliver Wendell Holmes gave his private library to the Boston Medical Library. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION recognized the occasion with special editorial notice and suggested to the members of the Association that they might have opportunity to meet the great American author and physician at the next meeting of the Association, which was to take place in Newport, R. I.

PROGRESS IN OBSTETRICS

Significant of the progress of medical science in that year was a lecture given to the Chicago Medical Society by Professor W. W. Jaggard of the Chicago Medical College. Jaggard was one of the greatest teachers of his day. Dr. Joseph B. De Lee derived from him the interest toward improvement in obstetrics which became his life work. The article on "The Prevention of Puerperal Fever" is a demand for thoroughgoing cleanliness which came closely on the demonstrations by Semmelweis and the argument of Oliver Wendell Holmes. Curiously, however, at the conclusion of his article Dr. Jaggard warned physicians to make sure that the woman who was giving birth should not be placed in a room in which there was "communication with the sewer, since vitiated air is unwholesome under all conditions of human life." He called attention, however, to an aphorism of Kucher, "I would be less frightened by the bursting of a sewer pipe during labor than by the use of a suspicious sponge or an unclean rag on the external genitals." And as a final conclusion, Dr. Jaggard said "These rules are simple and easy of application as well in private as in hospital practice; as well on South Halsted Street as on Calumet Avenue." It would interest Professor Jaggard, should he return today, to discover that South Halsted Street has now improved considerably over Calumet Avenue!

Following the resignation of Dr. John B. Hamilton, THE JOURNAL was issued by the Board of Trustees with the advice of N. S. Davis until June 26, when Dr. John H. Hollister of Chicago was elected editor.

PROGRESS OF THE ASSOCIATION

Toward the end of the year THE JOURNAL began a campaign for better control over licensure to practice in the individual states. The editor published a brief review of forty years in the history of the American Medical Association and he listed the following five chief accomplishments of those forty years:

> "First. By the early adoption of a Code of Ethics which commends itself to the approval of all medical men, it has

clearly defined the rules that should govern, not only among members of the profession, one with another, but also their relations with the people.

Second. It has fostered fraternal fellowship and helped to bring into close and friendly relation the medical men of all parts of this broad Union.

Third. It has always been the earnest advocate of a higher standard of medical education and in every way possible has sought to stimulate original investigation.

Fourth. Its influence has always been helpful to our medical colleges—and it has favored the maintenance of medical societies, both state and local, everywhere.

Fifth. For the purpose of assuring the closest possible relations with the masses of the profession—it even commits its own management to their delegates, as they shall come fresh from the local societies to express their will, from year to year, rather than to permanent members, who might in time misrepresent their constituencies.

The Association is in accord with the genius of American institutions. It is national in its representation and never sectional in interests. It is in no sense exclusive and yet makes ample provision for those who by reason of talent and culture may best serve the profession as instructors and guides. . . . "

In June the editor discovered that some one, taking advantage of the forthcoming annual session of the American Medical Association, began soliciting advertisement for something called "The American Medical Association Annual." It became necessary for the Association to disavow publicly any association with this dubious financial enterprise.

THE SPECIAL ISSUE

The Journal itself was, however, embarking on a financial enterprise to signalize the occasion that amazed the American medical publishing world. In anticipation of the 1889 convention The Journal of the American Medical Association issued an edition of 75,000 copies and mailed one to every physician in the United States. Its purpose was to attract a large number of physicians to the annual meeting in Newport. The other medical periodicals of the country paid compliments to the special issue. One contemporary called attention to the fact that The Journal was under temporary management and suggested that the Association could scarcely do better than to make the present arrangement permanent.

The final issue of the twelfth volume carried a plea for the sufferers from the Johnstown flood.

The next volume opened with the address of the President of the Association, Dr. W. W. Dawson of Cincinnati. He was concerned with the quality of medical teaching in the United States; with the quality of the young men who were to become medical students; he recognized that there would always be some doctors who were not as good as most of them. The University of Texas had just been liberally endowed. The universities of Virginia, Harvard, Yale, Princeton, Columbia and Cornell and the University of California had made enviable records, but there were now in the United States more than a hundred medical colleges and there was a feeling that medical colleges had increased too rapidly.

President Dawson urged an expansion of The Journal of the American Medical Association and a drive for more members. Great praise he poured on the Army Medical Library and Museum and on John Shaw Billings and his development of the *Index Catalogue*. "The medical profession," he said, "asks very little of the general government but it does ask that these two institutions shall be made as useful as possible." He saw looming as clouds on the horizon the gradual development of proprietary "patent" medicines which were in every sense of the word nostrums. He saw failure of states to set up systems of licensure as rapidly as they were needed.

The meeting in Newport was marked by many interesting features. Dr. William Pepper of the University of Pennsylvania gave the address on medicine and devoted it to the life of Benjamin Rush, but the treasurer of the Rush monument committee could only report a total of $1,000, and it was decided to abandon the $1 limit on subscriptions.

The Board of Trustees of the American Medical Association made its report on The Journal, recognizing that it had now become well established and a credit to the Association. At the beginning of the year the number of pages of The Journal had been increased from thirty-two to thirty-six weekly.

The American Social Science Association sent in a resolution, which was adopted, urging a more thorough general education antecedent to the study of medicine.

After the reading of the report of the Board of Trustees, the minutes show that Hon. George Bancroft, famous as a historian, entered on the stage and was presented to the members who arose to receive him.

At that time the resolution was adopted that the American Medical Association should send its representatives to the meeting of the U. S. Pharmacopeial Convention.

BROWN-SÉQUARD AND REJUVENATION

Among the extraordinary manifestations of our civilization is the manner in which a noted scientist who has gained great fame may suddenly hazard all his repute by some sudden aberration as he grows older. This occurred to the great Brown-Séquard, who suddenly claimed that he had discovered the secret of perennial youth and of rejuvenation. The Journal of the American Medical Association had recorded his utterances as too absurd to warrant serious consideration, but his ideas began to gain great public interest. The Journal then announced the report of a citizen who had met sudden death by attempting to rejuvenate himself by the Brown-Séquard technic.

ORGANIZATION

Still experimenting with methods of organization, there was now an attempt to gain strength and support for the American Medical Association by promoting reorganization with branches and societies similar to those of the British Medical Association. It was hoped that the districts and tristate and similar groups could be incorporated into the American Medical Association in some manner so as to assure a great membership with a vast subscription to The Journal. At the same time the California State Medical Association passed a resolution demanding that the one qualification necessary for membership should be continuous membership in a local medical society. This was the principle which was ultimately to prevail.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC CHYLOTHORAX RESULTING FROM BATTLE INJURY

LIEUTENANT COLONEL WILLIAM H. BERRY
Medical Corps, Army of the United States

Chylothorax is not a common condition. According to Brescia [1] it was first described by Bartolet in 1633. Jahsman [2] in a review of the literature extending up to 1942 was able to find only 102 cases. He reported 3 additional cases, bringing the total number to 105.

The following are the classifications of chylothorax: (1) traumatic; (2) obstructive or nontraumatic: (*a*) intraductile obstruction due to new growth, filaria or Hodgkin's disease, and (*b*) extraductile obstruction due to mediastinal tumors, tuberculous glands or aortic aneurysm; (3) associated diseases such as thrombosis of the subclavian vein, and (4) spontaneous.

The presence of a chylothorax is obvious when the pleura is perforated, as in the traumatic cases, but is difficult to explain when it is intact, as in the obstructive cases. The flow through the thoracic duct is only 4 mm. per second, and the pressure at its exit into the vein is less than the venous pressure. Curtis [3] quoted Sahli as advancing the theory that it passes through the lymphangiectasis by diapedesis. The passage of lymph might also be explained as being due first to diffusion or transudation, and second to rupture of dilated lymphatic vessels. This latter would appear to be a better explanation.

The spontaneous group of chylothorax occurs in children under 1 year of age and may be due to some congenital anomaly or atresia in the lymphatic system.

The case herein reported belongs to the traumatic group and is to my knowledge the only one in the military literature from the present war.

REPORT OF CASE

An infantryman aged 28 was wounded by an 88 mm. shell Nov. 17, 1944 in Germany. He was admitted to an army hospital with a pulse rate of 120 and blood pressure 70 systolic and 50 diastolic; he was in acute respiratory distress.

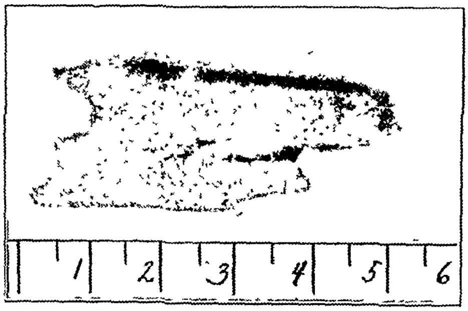
Physical examination revealed considerable emphysema over the upper part of the chest and neck. Percussion of the left side of his chest was dull, and there were diminished breath and voice sounds. The heart and mediastinum were not displaced. A roentgenologic examination of the chest revealed a fracture of the third rib anteriorly on the left side and a hemothorax. It also revealed a large shell fragment in the left side of the upper part of the chest. His left lung was aspirated and 600 cc. of blood was obtained. He was given a transfusion of 1,000 cc. of blood. His condition improved and the blood pressure stabilized at 110 systolic and 80 diastolic, but he continued to have respiratory distress and to need oxygen. Because of these symptoms and the large size of the missile, it was decided to perform a thoracotomy. This was done and the upper lobe of the left lung was found to have a laceration 2 inches (5 cm.) long, to be partially collapsed and to contain a moderately sized hematoma. A foreign body 2 by 5 by 5 cm., as shown in the accompanying illustration, had lodged in the posterior thoracic wall in the angle between the subclavian artery and the arch of the aorta. The missile was wedged tightly in the posterior wall of the chest. It had sharp, rough edges and was pressing firmly against the aorta and the subclavian artery. It appeared that the fragment might slough through these vessels if it was not removed, but there was also the danger that its removal might start a hemorrhage. Considerable traction had to be exerted to effect its removal, but hemorrhage did not occur. The laceration in the lung was sutured, the fractured rib ends were smoothed, blood clots were removed and the chest was closed.

The patient's condition remained good until forty-eight hours after the operation. By this time sufficient fluid had accumulated in the chest to cause dyspnea. A thoracentesis was performed and 800 cc. of milky, blood-stained fluid was removed. This was repeated forty-eight hours later, and 1,000 cc. of clear milky fluid was obtained. This was proved by laboratory examination to be chyle. One thousand cubic centimeters of chyle was obtained each day for the next eight days, after which the accumulation rapidly diminished. Five hundred cubic centimeters was obtained on the tenth day, and 75 cc. on the fourteenth day. During this period the patient lost 15 pounds (6.8 Kg.) and complained of considerable weakness. Recovery of weight and strength were rapid, and the patient was evacuated on his twentieth postoperative day.

The fluid obtained at the second tapping of the chest was strongly positive on examination for fat. The specific gravity was 1.020, the sugar content was 142.8 mg. and the nonprotein nitrogen 12 mg. per hundred cubic centimeters. A sample from the last tapping was examined, and the only change was a sugar of 76 mg. per hundred cubic centimeters. His blood chemistry was within normal limits. The hematocrit reading was taken five times, and the results ranged from 42 to 47.

COMMENT

It is interesting to note that the amount of chyle became decidedly less between the eighth and the tenth day. Lee [4] has shown that a fairly extensive collateral circulation becomes established between seven and eight days after the ligation of the thoracic duct, an observation which appears to be substantiated by this case.



Foreign body (2 by 5 by 5 cm.) removed from thoracic wall.

Wright [5] has expressed the opinion that lymph from the liver contains 6 per cent of protein as compared to 4 per cent in that from the intestine and 2 per cent in that from the legs, and that during starvation, there is at first a slight fall in the levels of blood sugar and proteins, but these soon become stabilized and remain so until near the end. He stated that the liver is reduced to 54 per cent of its bulk, the muscles to 31 per cent and the spleen to 60 per cent. When one considers the large bulk of muscle tissue and the relatively large volume of liver that can be called on, it is easy to understand how this patient's blood chemistry remained normal for a period of ten days.

The amount of chyle and lymph flowing through the thoracic duct is estimated to be between 50 and 120 cc. per hour. The patient lost about 1,000 cc. per day, which would roughly represent his total quantity from this source. He consequently must have been sustained from stored bodily reserves, and the liver and muscles seem to be the most likely sources.

The treatment of chylothorax is mainly supportive. Plasma should be given daily in amounts equivalent to the loss of chyle, and the fluid balance should be maintained. Intravenous infusions of the chyle from the chest of this patient were being considered when the drainage stopped. Surgical intervention

TRAUMATIC CHYLOTHORAX RESULTING FROM BATTLE INJURY

LIEUTENANT COLONEL WILLIAM H. BERRY
Medical Corps, Army of the United States

Chylothorax is not a common condition. According to Brescia[1] it was first described by Bartolet in 1633. Jahsman[2] in a review of the literature extending up to 1942 was able to find only 102 cases. He reported 3 additional cases, bringing the total number to 105.

The following are the classifications of chylothorax: (1) traumatic; (2) obstructive or nontraumatic: (*a*) intraductile obstruction due to new growth, filaria or Hodgkin's disease, and (*b*) extraductile obstruction due to mediastinal tumors, tuberculous glands or aortic aneurysm; (3) associated diseases such as thrombosis of the subclavian vein, and (4) spontaneous.

The presence of a chylothorax is obvious when the pleura is perforated, as in the traumatic cases, but is difficult to explain when it is intact, as in the obstructive cases. The flow through the thoracic duct is only 4 mm. per second, and the pressure at its exit into the vein is less than the venous pressure. Curtis[3] quoted Sahli as advancing the theory that it passes through the lymphangiectasis by diapedesis. The passage of lymph might also be explained as being due first to diffusion or transudation, and second to rupture of dilated lymphatic vessels. This latter would appear to be a better explanation.

The spontaneous group of chylothorax occurs in children under 1 year of age and may be due to some congenital anomaly or atresia in the lymphatic system.

The case herein reported belongs to the traumatic group and is to my knowledge the only one in the military literature from the present war.

REPORT OF CASE

An infantryman aged 28 was wounded by an 88 mm. shell Nov. 17, 1944 in Germany. He was admitted to an army hospital with a pulse rate of 120 and blood pressure 70 systolic and 50 diastolic; he was in acute respiratory distress.

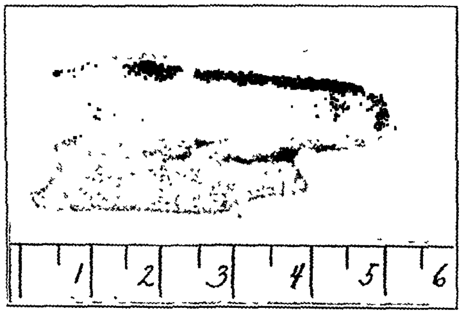
Physical examination revealed considerable emphysema over the upper part of the chest and neck. Percussion of the left side of his chest was dull, and there were diminished breath and voice sounds. The heart and mediastinum were not displaced. A roentgenologic examination of the chest revealed a fracture of the third rib anteriorly on the left side and a hemothorax. It also revealed a large shell fragment in the left side of the upper part of the chest. His left lung was aspirated and 600 cc. of blood was obtained. He was given a transfusion of 1,000 cc. of blood. His condition improved and the blood pressure stabilized at 110 systolic and 80 diastolic, but he continued to have respiratory distress and to need oxygen. Because of these symptoms and the large size of the missile, it was decided to perform a thoracotomy. This was done and the upper lobe of the left lung was found to have a laceration 2 inches (5 cm.) long, to be partially collapsed and to contain a moderately sized hematoma. A foreign body 2 by 5 by 5 cm., as shown in the accompanying illustration, had lodged in the posterior thoracic wall in the angle between the subclavian artery and the arch of the aorta. The missile was wedged tightly in the posterior wall of the chest. It had sharp, rough edges and was pressing firmly against the aorta and the subclavian artery. It appeared that the fragment might slough through these vessels if it was not removed, but there was also the danger that its removal might start a hemorrhage. Considerable traction had to be exerted to effect its removal, but hemorrhage did not occur. The laceration in the lung was sutured, the fractured rib ends were smoothed, blood clots were removed and the chest was closed.

The patient's condition remained good until forty-eight hours after the operation. By this time sufficient fluid had accumulated in the chest to cause dyspnea. A thoracentesis was performed and 800 cc. of milky, blood-stained fluid was removed. This was repeated forty-eight hours later, and 1,000 cc. of clear milky fluid was obtained. This was proved by laboratory examination to be chyle. One thousand cubic centimeters of chyle was obtained each day for the next eight days, after which the accumulation rapidly diminished. Five hundred cubic centimeters was obtained on the tenth day, and 75 cc. on the fourteenth day. During this period the patient lost 15 pounds (6.8 Kg.) and complained of considerable weakness. Recovery of weight and strength were rapid, and the patient was evacuated on his twentieth postoperative day.

The fluid obtained at the second tapping of the chest was strongly positive on examination for fat. The specific gravity was 1.020, the sugar content was 142.8 mg. and the nonprotein nitrogen 12 mg. per hundred cubic centimeters. A sample from the last tapping was examined, and the only change was a sugar of 76 mg. per hundred cubic centimeters. His blood chemistry was within normal limits. The hematocrit reading was taken five times, and the results ranged from 42 to 47.

COMMENT

It is interesting to note that the amount of chyle became decidedly less between the eighth and the tenth day. Lee[4] has shown that a fairly extensive collateral circulation becomes established between seven and eight days after the ligation of the thoracic duct, an observation which appears to be substantiated by this case.



Foreign body (2 by 5 by 5 cm.) removed from thoracic wall.

Wright[5] has expressed the opinion that lymph from the liver contains 6 per cent of protein as compared to 4 per cent in that from the intestine and 2 per cent in that from the legs, and that during starvation, there is at first a slight fall in the levels of blood sugar and proteins, but these soon become stabilized and remain so until near the end. He stated that the liver is reduced to 54 per cent of its bulk, the muscles to 31 per cent and the spleen to 60 per cent. When one considers the large bulk of muscle tissue and the relatively large volume of liver that can be called on, it is easy to understand how this patient's blood chemistry remained normal for a period of ten days.

The amount of chyle and lymph flowing through the thoracic duct is estimated to be between 50 and 120 cc. per hour. The patient lost about 1,000 cc. per day, which would roughly represent his total quantity from this source. He consequently must have been sustained from stored bodily reserves, and the liver and muscles seem to be the most likely sources.

The treatment of chylothorax is mainly supportive. Plasma should be given daily in amounts equivalent to the loss of chyle, and the fluid balance should be maintained. Intravenous infusions of the chyle from the chest of this patient were being considered when the drainage stopped. Surgical intervention has been advocated in the traumatic instances which do not close spontaneously. Dissection of the thoracic duct, however, is a difficult surgical operation and one that should be chosen only as a last resort.

SUMMARY

1. One case of war injury to the thoracic duct in the angle of the aorta and subclavian artery is reported.

2. The foreign body was removed from this location, and the patient recovered after the subsidence of traumatic chylothorax.

3. Some of the physiologic observations in connection with chylothorax are the establishment of a collateral circulation between the eighth and ninth days and the maintenance of normal blood chemistry.

4. The causes of the four types of chylothorax are trauma, obstruction of the ducts, thrombosis of subclavian vein and spontaneous rupture. Treatment consists in giving plasma and maintaining the fluid balance of the body.

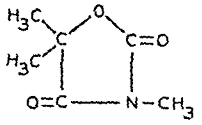
Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

TRIMETHADIONE. — Tridione — 3,5,5-Trimethyloxazolidine-2-4-dione — $C_6H_9NO_3$ — *M. W. 143.14.* The structural formula of trimethadione may be represented as follows:



Actions and Uses.—Trimethadione is primarily an anticonvulsant and has *only minor analgesic properties*. It is used in the treatment of epilepsy, in which it is principally effective in cases with seizures of the true petit mal type. Its results in this condition appear to be somewhat better in children than in adults. It is ineffective in grand mal. It is also useful in psychomotor epileptic seizures, especially with diphenyl hydantoin sodium when the latter alone is ineffective. It may be tried in myoclonic and akinetic seizures of organic origin but is generally less effective than *in the idiopathic forms* of the disease. It has been used with diphenyl hydantoin sodium and/or phenobarbital in cases in which attacks are complicated by grand mal seizures, but such use appears less rational and may in some instances serve to exaggerate the grand mal as the petit mal is decreased. It has been administered in solution by intramuscular injection to terminate attacks of status epilepticus, but such use is not of sufficiently established value to warrant recognition at the present time.

Toxic reactions to trimethadione appear to be relatively infrequent. Gastric irritation, nausea, skin eruptions, photosensitivity and blurring of vision with a diminution in visual acuity that is reversible may be encountered and are considered indications for temporary withdrawal or reduction in dosage of the drug. Photophobia appears to be less frequent in children than in adults. The skin manifestations that have been observed are not attributable to sensitization, and the visual disturbances have not been shown to be associated with optic nerve damage.

Rare cases in which aplastic anemia with a depression of all elements of the peripheral blood has occurred with the use of trimethadione indicate the need for repeated complete blood examinations in patients receiving this drug. It has been suggested that small initial doses be used and the patient cautioned to report at once any untoward symptoms that may ensue. Careful medical supervision of patients under treatment with trimethadione is essential. It should not be used in the presence of anemia, leukopenia or thrombocytopenia and employed with caution if at all in any type of blood dyscrasia.

It is contraindicated in patients with advanced renal or hepatic disease or with disease of the optic nerve.

Dosage.—*In petit mal epilepsy, the dosage required* may vary from 1 to 2 Gm. daily, given in divided doses of three to seven 0.3 Gm. capsules per day. In children under 6 years of age it is advisable to begin with 0.15 to 0.3 Gm. three times daily and to increase this if necessary. Optimum dosage must be determined *for each patient.*

Tests and Standards.—

Trimethadione occurs as a white, granular, crystalline substance possessing a slight camphor-like odor. It melts at 45-46.5 C. It is soluble in water and freely soluble in alcohol, in benzene, in chloroform and in *ether. The pH of a 5 per cent solution is about 6.0.*

Add 1 cc. of *one* normal barium hydroxide solution to 5 cc. of a 2 per cent aqueous solution of trimethadione: within *a few* seconds a considerable precipitate appears.

Add 3 cc. of 25 per cent *sodium* hydroxide to 0.5 Gm. of trimethadione. Heat for thirty minutes on a boiling water bath. Carefully evaporate the solution to 0.5 cc. over a free flame, during the *course* of which a heavy *precipitate* forms. Cool and carefully treat the residue with hydrochloric acid until the resulting solution is acid *to litmus*. Add 1 *drop of* ferric chloride solution to 10 drops of the aforementioned *solution*: a *deep yellow color* develops.

Extract the acid solution obtained as described in the preceding paragraph with three 10 cc. portions of ether. Decant the ether extracts *from* the residue *and combine all three ether fractions. Evaporate the* ether solution to dryness on the steam bath and then recrystallize *from* benzene: the *melting point* of the crystals is 79-81 C.

Accurately weigh about 10 mg. of the derivative *obtained* in the previous paragraph. Transfer to a 150 cc. beaker, add 3 drops of ethanol to *effect solution* and follow with about 25 cc. of water. Add two drops of phenolphthalein and titrate with one hundredth normal sodium *hydroxide*: the neutralization equivalent is within the limits 101-107.

Dry 0.5 Gm. of trimethadione, accurately weighed, over phosphorus *pentoxide for six hours*: the loss *does not exceed 0.1 per cent.*

Ash about 1.0 Gm. of trimethadione, accurately weighed: the amount of *residue is not more than 0.05 per cent.*

Weigh *accurately about 200 mg.* of trimethadione. *Dissolve in about* 5 cc. of alcohol and then add 25 cc. of water followed by 25 cc. of tenth-normal sodium hydroxide. Allow to stand for fifteen minutes, add 4 drops of cresolphthalein and titrate the excess alkali with tenth-normal hydrochloric acid. Each cubic centimeter of tenth-normal sodium hydroxide is equivalent to 0.014314 Gm. of trimethadione: the trimethadione content is not less than 98 per cent nor more than 102 per cent.

Trimethadione Capsules:

Weigh sufficient powder from ten capsules to contain about 100 mg. of trimethadione. *Transfer to a small beaker, add 5 cc. of 95 per cent* ethanol and allow to stand for five minutes. Decant the alcohol through filter paper previously moistened with alcohol. Repeat the extraction *with alcohol and filtration* twice more. Dilute the combined filtrates to four volumes with water. Add 20 cc. of tenth-normal sodium hydroxide to the solution, allow to stand for five minutes, add two drops of cresolphthalein and then *neutralize* the excess alkali with tenth-normal hydrochloric acid. Each cubic centimeter of tenth-normal *sodium hydroxide* is equivalent to 0.014314 Gm. of trimethadione: the trimethadione content is not less than 95 *per cent nor* more than 105 per cent of the claimed amount.

Trimethadione Solution:

Pipette *2 cc.* of trimethadione solution (*about 40 mg.* per cubic centimeter), add 50 cc. of water and then *20 cc.* of tenth-normal sodium hydroxide. Allow the trimethadione to hydrolyze for five minutes, add two drops of cresolphthalein and titrate the excess alkali with tenth-normal hydrochloric acid. Each cubic centimeter of tenth-normal sodium hydroxide used is equivalent to 0.014314 Gm. of trimethadione: the trimethadione content is *not less than 97.5* per cent nor more than 102.5 per cent of the claimed amount.

Abbott Laboratories, North Chicago, Ill.

Tridione Capsules: 0.3 Gm.

STREPTOMYCIN.—*Streptomycin is a purified active* principle produced by certain strains of Streptomyces griseus when they are grown on suitable mediums. It has the property of inhibiting the growth and of occasionally destroying certain gram-negative bacteria. It may be prepared as several salts, *including the hydrochloride and sulfate salts.*

Actions and Uses.—Streptomycin is an antibiotic agent. It is not a pure product but is marketed as a sterile powder in airtight ampules or vials, the activity in terms of milligrams or grams of pure streptomycin base being declared on the label. Streptomycin and its salts are reasonably stable but should be stored at a temperature not in excess of 15 C. Solutions of streptomycin are less stable than the dry powder and should always be kept in the refrigerator. *Only freshly prepared* solutions should be used parenterally.

Streptomycin is active in vitro against a wide variety of gram-negative organisms including such pathogens as Escherichia coli, Pasteurella tularensis, Hemophilus influenzae, Pseudomonas aeruginosa, Bacillus proteus, Eberthella typhosus and Brucella abortus. With certain outstanding exceptions, the *in vivo activity of streptomycin parallels its in vitro activity.*

Streptomycin is not appreciably absorbed when given by the oral route, although it is not significantly destroyed in the gastrointestinal tract. For systemic action it must be given by the parenteral route.

Streptomycin is useful in the treatment of urinary tract infections due to streptomycin-sensitive gram-negative organisms. In the presence of obstruction, streptomycin is of only temporary benefit, and successful therapy depends on correction of the underlying anatomic condition. Pasteurella tularensis is highly susceptible to streptomycin, and this agent is the most effective treatment for tularemia at present available. Influenzal meningitis due to various Hemophilus organisms has been successfully treated with streptomycin, as has Hemophilus infections in other parts of the body. Wound infections, bacteremias and other infections due to streptomycin-susceptible organisms may be treated with this agent.

Experience with streptomycin in the treatment of undulant fever, bacillary dysentery and typhoid has been disappointing, and failure of therapy has been the rule. Until further work elucidates the place of streptomycin in these infections, its use cannot be recommended.

Although streptomycin shows promising results in the therapy of tuberculous infections in guinea pigs, the clinical experience in human infections has not been sufficiently large to delineate its precise role in the control of human tuberculosis. At best it does not appear to offer more than limited usefulness as an adjunct to other forms of therapy.

Streptomycin is capable of producing side reactions of varying severity. Certain lots have been found which produce a histamine-like reaction on parenteral administration with a fall of blood pressure and syncope. This is due to some accompanying toxic material, and its occurrence is now rare. The most serious toxic effect is its neurotoxic action on the eighth nerve, which may occur in about 10 per cent of patients treated with large doses (3 to 4 Gm. daily) over periods of several weeks to months. This is characterized by vertigo, tinnitus, disturbance of equilibrium and diminished auditory acuity. On cessation of therapy, partial recovery of eighth nerve function is the rule, although this recovery is slow, and vestibular function appears to be permanently impaired although compensation occurs. Minor toxic effects include skin rashes, mild malaise, muscular aching and drug fever.

Dosage.—For intramuscular injection, the powder should be dissolved in sterile, pyrogen-free distilled water or isotonic solution of sodium chloride to give a concentration of from 100 to 200 mg. of streptomycin base per cubic centimeter. For subcutaneous injection, more dilute solutions are recommended. If the drug is administered by intravenous drip, 1 to 2 Gm. dissolved in a liter of isotonic solution of sodium chloride may be administered at a rate of about 25 drops per minute. For intrathecal administration, 10 to 20 mg. per cubic centimeter in isotonic sodium chloride solution should be used. For topical application, solutions containing 25 to 50 mg. per cubic centimeter may be used.

The dosage of streptomycin should be governed by the susceptibility of the organism responsible for the infection. In severe fulminating infections, doses of 2 to 4 Gm. daily may be necessary, given in divided doses, parenterally, every three hours. In less severe infections, and with highly susceptible organisms, daily doses of from 1 to 2 Gm. may be sufficient. Treatment should be continued for at least forty-eight to seventy-two hours after the temperature returns to normal and all signs of infection have disappeared.

It is important to give sufficiently large doses to inhibit or kill the infecting organisms quickly, since the development of "fastness" to streptomycin is common and may occur rapidly. Inadequate dosage predisposes to the development of resistant strains of the organisms.

Abbott Laboratories, North Chicago, Ill.

Streptomycin Sulfate: Vials containing streptomycin sulfate equivalent in activity to 1 Gm. of streptomycin base (one million units).

Merck & Co., Inc., Rahway, N. J.

Streptomycin Hydrochloride: Vials containing streptomycin hydrochloride equivalent in activity to 1 Gm. of streptomycin base (one million units).

Chas. Pfizer & Co., Inc., New York

Streptomycin Hydrochloride: Bottles containing streptomycin hydrochloride equivalent in activity to 0.375 Gm. of streptomycin base.

Streptomycin Sulfate: Bottles containing streptomycin sulfate equivalent in activity to 1 Gm. of streptomycin in base.

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies, 1946, p. 360).

The following article has been accepted:

Holland-Rantos Company, Inc., New York

Koromex Cream: 78 Gm. collapsible tubes. A water soluble stearic acid emulsion having a p_H of 4.2, prepared from the formula:

Stearic acid	20.0%
Cetyl alcohol	1.0
Glycerin	5.0
Boric acid	2.0
Oxyquinolin benzoate	0.02
Phenylmercuric acetate	0.02
Polyoxyalkalene sorbitan monostearate	3.0
Sorbitan monoöleate	5.0
Perfume	0.015
n-butyl-p-hydroxybenzoate	0.02
Water	q. s.

Packaged with a vaginal applicator or in refill packages containing a tube of cream only.

U. S. trademark 213,756.

Actions, Uses and Dosage.—See article Contraceptive Jellies and Creams.

Koromex Applicator: A transparent plastic syringe threaded at the blunt, intravaginal end, to screw onto the tubes of Koromex Cream, to permit filling by compression of the tube. The full capacity is 5 cc., the recommended dose.

THEOPHYLLINE (See New and Nonofficial Remedies, 1946, p. 395).

The following dosage form has been accepted:

E. S. Miller Laboratories, Inc., Los Angeles

Tablets Theophylline: 0.1 Gm.

Council on Physical Medicine Council on Foods and Nutrition and the Council on Pharmacy and Chemistry

The following statement is published for the information of manufacturers of accepted preparations and others who are concerned:

Howard A. Carter,
Secretary, Council on Physical Medicine.
J. R. Wilson,
Secretary, Council on Foods and Nutrition.
Austin Smith,
Secretary, Council on Pharmacy and Chemistry.

For a number of years the Councils have authorized the use of seals in connection with products which have been found eligible for inclusion as "accepted" in the publications of the respective bodies. It was recently pointed out that each of the seals emphasized the Association rather than the Council awarding the seal, a fact which it is believed gave rise to the erroneous impression that it is the Association rather than the individual Council that accepts a preparation or device. To correct this the seals were redesigned to emphasize the name of the Council concerned. Attention is called to the similarity of the seals, which intentionally indicates the corresponding similarity in methods of procedure, principles and objects of the three Councils. No change has been made in the rules governing the use of the seals. These rules appear in publications of the respective Councils. Cuts of the seals are available in three sizes. The following are reproductions of the largest size:

CALORIC INTAKE AND INDUSTRIAL OUTPUT

For years it has been assumed that the caloric needs of man were well understood. This assumption was based on the work of Rubner, Benedict, Lusk, Du Bois and others who with calorimeters diligently gathered the information needed for the calculation of caloric needs of both individuals and groups.

In the recent war opportunities developed for studying large groups of men over extended periods. Individual experiments in the past had often been done under circumstances that left doubts as to the rigor with which the given diet was observed. The war, however, created situations in which whole groups became completely dependent on strictly rationed supplies. Studies made under these conditions have corroborated observations previously made by slow, painstaking calorimetric studies on individuals.

Kraut and Muller[1] have related the caloric intake of workers to their industrial output. Their observations confirm some accepted beliefs about the human body. The body is often compared to a machine, and to it the law of the conservation of energy is assumed to apply in a rough sort of way. Accordingly the energy derived from ingested food is distributed between two functions, one the function of keeping the body alive at a certain basic level of weight and lesser activity, the other the function of carrying out additional work, exercise or play. The authors provide figures for miners, steel workers and others on strict rations to show that this distribution did occur in groups studied during the war, when rations in Germany were often reduced below the basic requirements. In their observations the authors divide the caloric intake into two portions according to their role, from 1,600 to 1,800 calories for basic needs and an additional portion for work. One group of 20 workmen, fed entirely by the factory management, were occupied with the erection of an embankment inside the works. Observations covered more than a year, during which it was shown that production, as measured in tons per unit of time, depended directly on available work calories. When work did not consume all the ingested calories, a mass weight gain was recorded. When production was stimulated by a premium of tobacco, a mass weight loss was recorded. This showed that, if output surpassed the range of caloric possibilities, the deficit had to be met by withdrawal of energy from body substance. As long as a worker received calories above the basic level, he unconsciously adjusted his activity to maintain his weight. If he received nothing above the basic level, adjustment was not possible other than weight loss in proportion to work. This clearly brought out the plight of civilian groups such as housewives, in whom any activity above the basic level caused prompt loss of weight. Miners and steel workers also were studied. The longest and most remarkable study had to do with the relation between nutrition and coal production of the Ruhr district from September 1939 to September 1944.

Assuming the correctness of these records, it is apparent why, on a starvation diet, the capacity to work is lowered and work finally stops entirely. The reason for the fall in coal production in the Ruhr during the war is quite clear. A small number of well fed men can produce more than a large number of men on subminimal diets, and attempts to maintain crews of starving men are sheer waste. An obvious contemporary application of these facts is to the feeding of prisoners of war. According to statements widely publicized in American newspapers, thousands of men, denied repatriation at this late date, are still being required to do heavy physical work on inadequate diets. This policy is stupid.

---

ADVANCES IN THE STUDY OF HEMOLYTIC STREPTOCOCCI

In a review of modern methods of studying hemolytic streptococci Swift[1] points out that military medical practice offers opportunities for the study and control of acute streptococcic diseases now not usually or easily available in civil practice. During the war frequent outbreaks among recruits of infections, especially respiratory, due to hemolytic streptococci led to well organized studies of these important organisms. The term hemolytic streptococci indicates that certain cocci which grow in chains can cause lysis or laking of red blood corpuscles. On the basis of other biologic properties, notably serologic or antigenic reactions and pathogenicity in different species of animals, these streptococci are divided into several distinct groups. The serologic grouping (Lancefield) depends on the elaboration by each group of a specific antigenic carbohydrate, the C substance. Group A contains the chief hemolytic streptococci pathogenic for man. This group is divided into types by means of agglutination and the precipitin reaction, each dependent on the presence in the cocci of specific protein components. The serums of animals immunized with virulent strains are used for the typing of group A. So far some forty types of this group have been recognized. It is said[1] that over 90 per cent of the strains recovered from army and navy trainees were composed of ten to twelve types.

---

[1] Swift, H. F.: Modern Technics for Studying Hemolytic Streptococci, Bull. U. S. Army M. Dept. **6**: 428 (Oct.) 1946.

Alice Evans[2] and others found that certain types of group A tend to be associated with particular streptococcic infections, but the distribution of types varies. At a given time and place a definite type may predominate, but shifting occurs from season to season and from place to place. Here many factors are involved which as yet are not understood.

Patients who recover from infection with a given type of group A will be immune for some time as a rule to reinfection by that type but perhaps subject to infection by other types. In other words, each type of streptococcus A infection is a distinct disease; consequently isolation in streptococcic infections should be practiced accordingly. Observations in the armed forces have established that cross infections readily occur when patients with different types of streptococcic infections are in the same ward. In any series of streptococcic infections prompt typing is needed in order to determine whether the infections are by different types of streptococci or an outbreak due to a virulent strain of a single type requiring immediate control. Typing will be of value also in the handling of the streptococcus carrier. Is he potentially dangerous or relatively harmless? The type of streptococci he carries in his nasal and throat secretions must be determined. If they belong to other groups than A or grow in so-called glossy colonies they may be of little importance in spreading infection. Swift says that "it is now obvious that a person should not be condemned as a disease disseminator merely because hemolytic streptococci can be recovered from his nose and throat." Typing is of essential importance also in the determination of the resistance of strains of certain types of hemolytic streptococci to sulfonamide compounds, penicillin and perhaps other antibiotics.

The interpost spread by troop transfers of similar respiratory epidemics due to a specific sulfonamide resistant strain of type 17 has been well studied.[3] Facilities should be available for streptococcus grouping and typing as well as for the determination of antibiotic resistance. Before the mass administration of sulfadiazine, for instance, it should be determined that the streptococcus strain involved in the outbreak is not sulfonamide resistant. The wide incidence of resistant strains makes this precaution essential. The results of newer methods of studying hemolytic streptococcus infections in military medical practice indicate that the general application of these methods will advance the understanding and control of the streptococcic diseases in civil practice also.

EPIDEMIOLOGIC PNEUMOCOCCIC PNEUMONIA

The scant information on the epidemiology of pneumococcic pneumonia as compared with the wealth of information as to its causative organism, the clinical course and the therapy can be accounted for, according to Hodges and MacLeod,[1] by the great difficulty of sufficiently controlling a civilian population so that exact relationships can be worked out between the many epidemiologic factors which contribute to the incidence of this disease. These authors investigated an epidemic of pneumococcic pneumonia at a technical training school of the Army Air Force between December 1942 and April 1945. The incidence of pneumonia at this school was higher than for other schools in the Technical Training Command of the Army Air Force and greatly in excess of the rates experienced by the Air Force as a whole.

Pneumococcus type II was the predominant organism over the entire period, causing approximately 35 per cent of all cases of pneumonia. Types I, V, VII, XII and IV were responsible for large numbers of infections and should be considered also as epidemic types. The uniformity of the population with respect to age and length of service in the Army, as well as the circumstances under which the men lived and worked, afforded an excellent opportunity for epidemiologic investigation of respiratory infections. The study of the population characteristics influencing the incidence of pneumococcic pneumonia revealed that the length of military service and duration of stay in the technical school played their part. Spread of respiratory infections by means of classrooms appears to be of greater importance than spread in barracks. This conclusion is supported by the observation that respiratory diseases affected the entire population in uniform fashion without any evidence of foci in individual barracks or squadrons. The maintenance of high rates for pneumococcic pneumonia was favored by close contact in classrooms during hours on duty as well as in the barracks. The incidence of pneumococci in classroom and barrack dust was approximately the same. The types of pneumococci predominant in the dust were the same as those present in the pharynx of normal men. Previous geographic environment, age, chilling or fatigue did not appear to be an important factor in the production of pneumococcic pneumonia in the population as a whole.

---

[1] Hodges, R. G., and MacLeod, C. M.: Epidemic Pneumococcal Pneumonia: I. Description of the Epidemic, Am. J. Hyg. 44:183 (Sept.) 1946; II. The Influence of Population Characteristics and Environment, ibid., p. 193; III. Pneumococcal Carrier Studies, ibid., p. 207; IV. The Relationship of Nonbacterial Respiratory Disease to Pneumococcal Pneumonia, ibid., p. 231. This investigation was a joint project of the Commission on Pneumonia, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the United States Army, Office of the Surgeon General, United States Army, and the Army Air Force Rheumatic Fever Control Program, Office of the Air Surgeon.

Pneumococcus carrier studies revealed that the carrier rate for all types combined varied with the seasons, being considerably higher during the winter months than during the spring or summer. The carrier rate did not bear a close relationship to the incidence of either nonbacterial respiratory disease or pneumococcic pneumonia. The carrier rates for certain of the infective types of pneumococcus, especially types IV and XII, showed a good correlation with the incidence of pneumonia caused by these types. A high carrier rate for infective types, however, did not by itself account for the incidence of pneumonia caused by these types. New arrivals at the post carried relatively few of the infective types of pneumococcus but rapidly acquired them during the first six weeks of their stay. The peak incidence of pneumonia occurred during the same period. The authors believe that a high carrier incidence for pneumococcus types I, II, V, VII, XII and IV was built up during the first winter season after the opening of the technical school and that these types were passed on to succeeding generations of students for the next three years. It seems probable that a decrease in the carrier incidence of the first four types occurred during the 1944 to 1945 season as a consequence of specific immunization against these types. Evidence was obtained which indicates strongly that pneumococci did not cause common upper respiratory disease, at least on any considerable scale.

Over a three year period of study 1 patient with pneumococcic pneumonia was admitted to the hospital for every 10 patients with nonbacterial respiratory disease. A higher ratio occurred shortly after the technical school was opened, presumably because the population had not yet become saturated with the infective types of pneumococci. During a period when pneumococcus type II was causing a large proportion of cases of pneumococcic pneumonia the ratio was lower. Evidence was not obtained that either influenza A or influenza B caused greater predisposition to pneumococcic pneumonia than other nonbacterial respiratory infections. The highest incidence of pneumococcic pneumonia, occurring when influenza A or B was epidemic could be explained on the basis of the large number of cases of nonbacterial respiratory disease caused by these viruses. The ratio of pneumonia to nonbacterial respiratory disease remained approximately 1 to 10. A consistent relationship could not be found between the incidence of pneumococcic pneumonia and streptococcic respiratory disease. Furthermore, the rates for streptococcic disease showed no obvious relation to nonbacterial respiratory disease.

From the data presented in these papers it is apparent that a simple explanation of the extremely high pneumonia rates encountered at the technical school is not possible. The high incidence appears to have been the result of a number of factors. In December 1942 and January 1943 the population of the technical school became heavily seeded with pneumococci. Prior to that time there had been relatively little pneumococcic pneumonia despite high rates for nonbacterial respiratory disease. From the beginning of 1943 until April 1945 pneumococcic pneumonia was prevalent in the technical school. The infective types of pneumococci were apparently passed along from one generation of students to another. Evidence for this is to be found in the similarity of the three winter seasons in the distribution of types of pneumococci causing pneumonia, allowing for the modification in distribution which resulted from immunization with the capsular polysaccharides during the 1944 to 1945 season. The authors assume that the presence in the population of large numbers of virulent pneumococci was one of the principal factors in the production of high pneumonia rates. The environmental conditions existing in the technical school, the constant flow of new susceptibles through the school and the thorough mingling of the school population all favored the spread of respiratory diseases. The same factors almost certainly contributed to the dissemination of pneumococci.

Current Comment

MEDICINE SERVES AMERICA

Electrical transcriptions prepared by the Bureau of Health Education have now been in use by county medical societies, state societies, health departments and other agencies for practically three years with conspicuous success. The first full year of such local broadcasting from "platters" brought about just under 3,000 local broadcasts; the second year witnessed an increase to approximately 4,500 such broadcasts. A new series of transcriptions entitled "Medicine Serves America" is announced on page 326 of this issue of THE JOURNAL. One of the disadvantages of electrical transcriptions is their fixed character. They are not subject to revision. The rapid pace of medical progress might outdate a set of transcriptions during the time between the beginning of preparation and the delivery of the finished product. In the series "Medicine Serves America" the Bureau of Health Education believes that it has overcome this disadvantage. This series, unlike the other series, is not devoted to a single topic but is a miscellaneous collection of subjects. The list of its titles will vary from time to time. Material of current interest will be included while it is fresh and will be dropped as quickly as it becomes outdated.

THE ALLERGIC PULMONARY REACTIONS OF LOEFFLER'S SYNDROME

Loeffler's syndrome[1] is characterized by changing, even transitory, pulmonary infiltrations, eosinophilia of the blood and sputum, and a relatively mild clinical course, usually afebrile, in contrast to the roentgenographic appearances in the lungs. Frequent x-ray examinations are necessary to understand the changes in the lungs. Many clinical reports of such cases have been published. In most of these reports the syndrome is explained as an allergic response in the lungs to various allergenic substances, including the tubercle bacillus, pollens, Endameba histolytica, the larvae of Ascaris lumbricoides, trichinae, and nematodes of cutaneous helminthiasis.[2] Fleeting pulmonary consolidations have been described in association with sulfonamide treatment,[3] brucellosis, asthma, amebiasis and trichiniasis. The structural alterations in the lungs at various stages of the syndrome have not been described adequately. The changes in the few cases examined after death appear to support the allergic explanation, and they may be summarized as bronchitis and pneumonia, lobular and interstitial, with pronounced eosinophilia in the exudation and infiltration coupled with appreciable increase of eosinophils in the blood. In a case of Loeffler's syndrome in a woman aged 59 with "symptomatic nonspasmodic 'asthma' of seven years' duration" there were large numbers of eosinophils in the pneumonic exudate, granulomatous and fibrous changes with necrotic arteritis and phlebitis of the allergic type.[4] Much remains to be learned about the pulmonary reactions of Loeffler's syndrome. Perhaps granulomatous processes in other organs, e. g. eosinophilic granuloma of bone, may also be allergic.

SUDDEN DEATH IN YOUNG MEN

The Army Institute of Pathology received reports between 1942 and 1946 of approximately 1,000 sudden nonaccidental, noncombat deaths of apparently healthy soldiers aged 18 to 40. Pathologic examination of between 700 and 800 of these, reviewed by Moritz and Zamcheck,[1] reveals that approximately 350 of the deaths were caused by previously unrecognized heart disease, almost 300 of which were due to coronary arteriosclerosis. The postmortem examinations disclosed severe atherosclerosis of one or both coronary arteries, and thrombotic occlusion was recognized in approximately 25 per cent. Of the 91 cases involving sudden death from nontraumatic intracranial hemorrhage the bleeding was principally subarachnoid and appeared to have resulted from ruptured aneurysm of congenital or berry type in 69. Also included as a cause of sudden death was meningococcemia, in some cases of which death occurred within twenty-four hours after onset of incapacitating symptoms. This group included 110 cases of the 350 fatal meningococcic infections reported. The records of 95 of these were sufficiently complete to analyze. Purpura or cutaneous petechiae were recognized in over 80 per cent. Focal or massive adrenal hemorrhages were encountered in 71 per cent. The authors believe that adrenal hemorrhage in fulminating meningococcemia is usually preceded by degenerative changes in the cells of the glomerular and fascicular zones of the cortex. Some 200 to 400 sudden deaths were classified as due to miscellaneous causes. The largest single cause was infection of the respiratory tract. Other causes included aortic rupture, encephalitis, nonmeningococcic meningitis and pulmonary tuberculosis. At least 140 sudden deaths were investigated in which the postmortem observations disclosed nothing abnormal.

"DR. GRAHAM AND FAMILY" GOES ON THE AIR

Through the cooperation of the Mutual Broadcasting System the American Medical Association will start on February 3 a program under this title, announced in detail on page 326 of this issue of THE JOURNAL. The program will be devoted to a portrayal of the family doctor as he lives and practices in a fictitious but typical average middle size American city set in the midst of an imaginary rural area. Such city-county combinations are the backbone of the nation. In such areas practice a vast majority of American physicians serving their patients in sickness and in health and contributing to the life of the community as only professionally trained citizens can. The form and type of the program will be entertainment somewhat after the manner of the radio feature "One Man's Family." The doctor will be portrayed primarily as a man in the setting furnished by his family, his practice and his community. This is an interpretative rather than an educational program. Nevertheless the glimpses of medicine that will show through will be modern and informative. The broadcasts will originate from New York. There will be no speaker. The dramatization will be permitted to create its own impression. The establishment of this new program in no way affects the broadcasts under the title "Doctors—Then and Now" by the National Broadcasting Company. Neither does it preclude the possibility of additional radio arrangements. The electrical transcription services will be continued. All are under the supervision of the Bureau of Health Education.

ORGANIZATION SECTION

Official Notes

NATIONAL CONFERENCE ON RURAL HEALTH

The second annual meeting of the National Conference on Rural Health will take place at the Palmer House, Chicago, Friday and Saturday February 7 and 8. In line with the purpose of the conference, to discuss ways and means of improving *rural medical service, the following program has been prepared:*

Palmer House, Friday Morning

9: 00 A. M. *Registration*
Red Lacquer Room
9: 45—9: 55 A. M. *Purpose of Conference*
F. S. Crockett, M.D., Chairman, Committee on Rural Medical Service American Medical Association
9: 55—10: 00 A. M. *Address of Welcome*
George F. Lull, M.D., Secretary and General Manager, American Medical Association
10: 00—10: 15 A. M. *The Farmer and the Medical Service Program*
Albert S. Goss, Master, the National Grange, Washington, D. C.
10: 15—10: 55 A. M. *Methods of Bringing and Holding Doctors in Rural Areas*
Chester Starr, Director of Rural Health, Missouri Farm Bureau Federation, Jefferson City
10: 55—11: 35 A. M. *Hospital Facilities and Health Centers for Rural Areas*
Mrs. Roy C. Weagly, President, the Associated Women of the American Farm Bureau Federation, Hagerstown, Md.
Graham L. Davis, Director, Division of Hospitals, W. K. Kellogg Foundation, Battle Creek, Mich.; Member Federal Hospital Council
Joseph W. Fichter, Master, Ohio State Grange, Columbus
Robin C. Buerki, M.D., Dean, Graduate School of Medicine, University of Pennsylvania, Philadelphia; Member Federal Hospital Council
11: 35—11: 45 A. M. *Intermission*
11: 45—12: 30 A. M. *Voluntary Medical Prepayment Plans as They Apply to Rural Communities*
Edward Mertz, Director of Education, Farmers Educational and Cooperative Union of America, Denver
James R. McVay, M.D., Vice Chairman, Council on Medical Service, American Medical Association, Kansas City, Mo.
J. S. Jones, Secretary, Minnesota Farm Bureau Federation, St. Paul

F. S. Crockett, M.D., Chairman.

A. M. A. Headquarters, Friday Afternoon

ROUND TABLE DISCUSSIONS *

2: 00—5: 00 P. M.
1. *Hospital Facilities and Health Centers*
   Allen T. Stewart, M.D., Chairman
   Mrs. Roy C. Weagly, Co-chairman
2. *Methods of Bringing and Holding Physicians and Dentists in Rural Areas*
   J. S. Jones, Chairman
   H. B. Mulholland, M.D., Co-chairman
3. *Voluntary Medical Prepayment Plans*
   James F. Doughty, M.D., Chairman
   Mrs. Paul Palmer, Co-chairman
4. *Nursing Needs of Rural Communities*
   Mrs. Chas. W. Sewell, Chairman
   Chas. W. Holman, Co-chairman
5. *Health Council as Agency for Promoting Rural Health*
   J. Paul Jones, M.D., Chairman
   Lloyd C. Halvorson, Co-chairman
6. *Medical Care for Lower Income Groups*
   Owen Cooper, Chairman
   Edward Mertz, Co-chairman

Palmer House, Red Lacquer Room,

Saturday Morning

9: 30 A. M. *Reports of Round Table Committees and Discussion*
1: 00 P. M. *Luncheon*
Speakers:
Hon. J. Melville Broughton, Raleigh, N. C.
Harrison Shoulders, M.D., President, American Medical Association
Olin West, M.D., President-elect, American Medical Association

L. W. Larson, M.D., Co-chairman.

ADDITIONAL ELECTRICAL TRANSCRIPTIONS

The Bureau of Health Education of the American Medical Association announces a new series of electrical transcriptions under the title "Medicine Serves America," available about February 15. This makes the fifteenth series of transcriptions and provides a transcription library which is now large enough to keep a local medical society broadcasting once a week for almost four years. In this series are included interviews, dramatizations, musical programs and a wide variety of subjects. The new series consists of these programs:

1. Training Good Doctors, Dr. Victor Johnson.
2. Hardening of the Arteries, Dr. W. C. Hueper.
3. Cancer in Industry, Dr. A. J. Lanza.
4. Modern Treatment of Skin Diseases, Dr. W. W. Bolton.
5. Farm Accidents, Dr. H. H. Young.
6. Modern Progress in Drugs, Dr. E. M. K. Geiling.
7. Infectious Heart Disease, Dr. Walter S. Priest.
8. Woman's Auxiliary to the American Medical Association, Mrs. J. D. Hamer and Mrs. E. A. Allen.
9. Protecting the Public, Dr. Austin E. Smith.
10. Health and Physical Fitness, Dr. Dean F. Smiley and Fred V. Hein, Ph.D.
11. Teamwork in Cancer in Industry, Dr. T. J. Curphey.
12. Working Toward Sound Minds, Dr. Roy R. Grinker.
13. New Hope for the Deafened, Dr. Norton Canfield.
14. The Soul of Medicine, Dr. Harrison Shoulders.

Full information is contained in a radio handbook published by the Bureau of Health Education and available in single copies free to medical societies, health departments and voluntary health agencies when requested on official letterheads. This manual is not primarily designed to be sold, but, if quantities are desired, a nominal price will have to be put on it. Such prices are available on request from the Bureau of Health Education, 535 North Dearborn Street, Chicago 10.

MEDICAL BROADCAST ON MUTUAL NETWORK

Beginning Monday February 3 the American Medical Association and the Mutual Broadcasting System will present a thirty minute dramatic presentation entitled "Dr. Graham and Family" each Monday at 10:30 p. m. Eastern standard time (9:30 Central, 8:30 Mountain, 7:30 Pacific standard time). The show will run for twenty-six weeks.

This will be a running story of the life of a general practitioner in a medium size typical American community. It will portray the doctor's practice and the life in his home and his community relationships. It will have only such medical aspects as will come in naturally because the leading character is a doctor. The purpose of the broadcasts is not so much educational as interpretative.

Plans for the program have been made by Drs. W. W. Bauer and W. W. Bolton of the Bureau of Health Education with Mr. Phillips Carlin and "Bud" Fischell of the Mutual network. The scripts will be written by Allen Sloan and the production directed by Cyril Ambruster.

TELEVISION PROGRAMS

The following television programs have been arranged by the Bureau of Health Education for presentation over Station WBKB, Chicago, on the dates indicated:

February 13.	Psychosomatic medicine. Special Navy film.
February 27.	Plastic eyes and contact lenses. Miriam D. Eubank, M.D., Evanston, Ill.
March 13.	Oral surgery. Lon W. Morrey, D.D.S., American Dental Association, Chicago, and a representative from the Chicago Society of Oral Surgeons.
March 27.	Centennial of American Medicine — Physical Medicine. C. O. Molander, M.D., Chicago, and Howard A. Carter, Ph.D., Secretary, Council on Physical Medicine.

---

* Recommendations of round table committees regarding dentistry and nursing will not be acted on by the Conference but will be referred to the National Organizations concerned.

VICTOR JOHNSON ACCEPTS APPOINTMENT WITH MAYO FOUNDATION

The Board of Regents of the University of Minnesota, the Board of Governors of the Mayo Clinic and the Graduate Committee of the Mayo Foundation have announced the appointment of Dr. Victor Johnson of Chicago to the post of director of the Mayo Foundation for Medical Education and Research to succeed Dr. Donald Balfour when he becomes Director Emeritus in 1947. Dr. Johnson will also be professor of physiology.

Dr. Johnson will join the staff of the Mayo Foundation in April and will become director in October, with Dr. Balfour continuing in an advisory capacity.

Washington Letter

(From a Special Correspondent)

Jan. 29, 1947.

President Truman Thanks Scientists for Wartime Research

President Truman expressed his thanks at White House ceremonies to the scientists who conducted wartime research in the Office of Scientific Research and Development, which is now being disbanded by Dr. Vannevar Bush, director. In the group were Drs. Bush; A. R. Dochez of Columbia University; Alfred N. Richards, chairman, Committee of Medical Research and Development; A. Baird Hastings, of the department of biochemistry of Harvard Medical School; Lewis H. Weed, National Academy of Science; Karl T. Compton, president, Massachusetts Institute of Technology; James B. Conant, president, Harvard University; J. C. Hunsaker, M. I. T.; Roger Adams, University of Illinois; Richard Tolman, California Institute of Technology, and Frank B. Jewett, National Defense Research Committee.

Nuclear Research for Medical and Public Health Work

Leon F. Curtiss, chief, radioactivity section, U. S. Bureau of Standards, outlined joint plans of the bureau and of the U. S. Public Health Service to erect a 20 million dollar national radiation institution at Bethesda, Md. It would be devoted to peacetime research in nuclear energy for public health work and the development of scientific methods for everyday use of radioactive substances. The project has been recommended to the President's Atomic Energy Commission, which has the job of coordinating atomic energy research and has taken offices in the new War Department building in downtown Washington. The program, which would require approval of Congress, would include large laboratories and a uranium pile valued at three million dollars. The project would not study development of atomic energy for war services but would concentrate on research in radioactivity, radiobiology and nuclear energy in general for protection of health.

Health Welfare Programs in Labor-Management Agreements

Labor Secretary Schwellenbach in his annual report to Congress advocated increased use of health-welfare programs in labor-management agreements as "an effective and flexible means of providing greater social security through collective bargaining." He believes that health-welfare programs will assure greater industrial harmony and worker security. John L. Lewis, president of the United Mine Workers, obtained such a fund but wants to increase the industry's contribution to the mine welfare fund from 5 to 10 cents a ton. The C. I. O. "Big Three," steel, automobile and electrical workers unions, are asking for employer financed welfare programs in 1947 wage contracts.

Courses in Mental Hygiene Proposed for Military Academy

Dr. William C. Menninger, formerly chief of the Army Neuropsychiatry Consultants Division and now chairman of consultants to the Secretary of War, revealed here that the Surgeon General of the Army has proposed that mental hygiene be added to the curriculum of the U. S. Military Academy. In Washington with other of the nation's leading psychiatrists to determine how to improve the Army's program, Dr. Menninger said the courses would be adopted to train better leaders. He expressed the opinion that if soldiers had better leaders and more pride in their army jobs there would be fewer breakdowns.

Red Cross Spends Seven Hundred and Thirty Million Dollars in Seven Years

National Chairman Basil O'Connor of the American Red Cross reports that 730 million dollars has been spent by the organization in the last seven years. He described the period as the "most significant" in the history of the Red Cross and listed among the numerous services performed at home and abroad the furnishing of drug, medical and educational supplies and the reorganization of community health and welfare services in war-affected cities. He also reported that 6,663,121 Americans gave 13,326,000 pints of blood in the donor program for the Army and Navy.

Model Center for Rehabilitation of Handicapped Civilians

Dr. Howard Rusk, former chief of Army Air Forces rehabilitation, told a Washington group which included Mrs. Harry S. Truman and wives of cabinet members that there is need for a model center where civilians with physical handicaps could be given the same kind of rehabilitation accorded wounded servicemen and veterans. A drive for $300,000 has been launched. Dr. Rusk pointed out that while the government is gratefully assisting disabled veterans to retrain themselves for useful lives, 23 million civilians also need rehabilitation. He said that twenty-five communities are setting up rehabilitation centers but require a model center.

Promote Nationwide Recruitment of Student Nurses

The Council of Professional Practice of the American Hospital Association has proposed that a nationwide committee be established to promote student nurse recruitment. Dr. Robin C. Buerki, chairman, said that the existing shortage of graduate nurses and low enrolment of students are affecting hospitals, industry, schools, community health organizations, private physicians and local and federal health agencies. The War Department announced that it had given the rank of second lieutenant to 300 nurses with no military experience to meet the acute shortage of nurses.

Three Antivivisection Bills Introduced in Congress

Three bills have been introduced in the 80th Congress which oppose, directly or indirectly, scientific experimentation on animals. House Resolutions 207 and 208, presented by Representative Bradley, Republican of Michigan, would punish persons transporting and receiving stolen dogs in interstate commerce and would prescribe penalties for keeping, injuring and destroying dogs in the District of Columbia. House Resolution 462, submitted by Representative Lemke, Republican, of North Dakota, prohibits "experiments on living dogs in the District of Columbia.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

National Conference on Rural Health, Chicago, Feb. 7-8. Dr. F. S. Crockett, 535 N. Dearborn St., Chicago 10, Chairman.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Earlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Cancer Research

Senator Pepper has reintroduced, as S 93 his bill to authorize the President to undertake to mobilize at some convenient place in the United States an adequate number of the world s outstanding experts and coordinate and utilize their services in a supreme endeavor to discover means of **curing and preventing cancer.** Similar bills have been introduced in the House by Representative Dirksen, Illinois, as H R 100, by Representative Rooney, New York, as H R 292, and by Representative Douglas, California, as H R 780

Representative Stevenson, Wisconsin has also introduced a bill, H R 977, to provide for the mobilization of the scientific resources and knowledge of the United States for the purpose of seeking the causes and cure of **cancer, poliomyelitis** and certain other degenerative diseases *of mankind*

Dental Health Programs

A bill introduced by Senator Pepper, Florida, for himself and Senator Murray, Montana, and Senator Aiken Vermont, S 178, proposes to amend the Public Health Service Act so as to provide assistance to states in developing and maintaining **dental health programs.**

Another bill S 176, introduced by Senator Murray, Montana, for himself and Senator Pepper, Florida, Senator Taft, Ohio, Senator Aiken, Vermont, and Senator Morse, Oregon, would provide for, foster and aid in coordinating research relating to **dental diseases** and conditions A similar bill has been introduced in the House by Representative Harris, Arkansas, as H R 574

National Science Foundation

Representative Celler, New York, has introduced H R 942, proposing to enact the "National Science Foundation Act" to promote the progress of science and the useful arts, to secure the national defense and to advance the **national health and welfare** It would establish a National Science Foundation to be administered by an administrator appointed by the President, by and with the advice and consent of the Senate In the foundation there would be a Division of Mathematical and Physical Sciences, a Division of Biological Sciences, a Division of Social Sciences, a Division of Health and Medical Sciences, a Division of National Defense, a Division of Engineering and Technology, a Division of Scientific Personnel and Education, a Division of Publications and Information and such other divisions, not to exceed three in number, as the administrator from time to time may establish after receiving the advice of a National Science Board

Water Pollution Control

Several bills have been introduced to provide for **water pollution** control activities H R 123, introduced by Representative Mundt South Dakota, H R 315, introduced by Representative Spence, Kentucky, and H R 470, introduced by Representative Elston, Ohio These bills would authorize the Surgeon General of the Public Health Service, in cooperation with other federal agencies and with state health authorities and interstate agencies, and with municipalities and industries, to prepare comprehensive programs for eliminating or reducing pollution and improving the sanitary condition of the surface and underground waters in or adjacent to any state Grants-in aid and loans would be made available

Control of Barbiturates

A bill introduced by Representative Rogers, Massachusetts, H R 588, proposes to bring the **barbiturates** within the purview of the federal *narcotic laws*

Miscellaneous

A bill introduced by Representative Lane, Massachusetts, H R 260, proposes to credit to active and retired officers of the Medical Department of the Army all service performed as **interns** in army hospitals on a civilian-employee status

The construction of a **hospital for the insane** of Alaska would be authorized by H R 196, introduced by Delegate Bartlett, Alaska

H J Res 15 introduced by Representative Judd, Minnesota, would designate the week of February 14 in each year as **National Heart Week** and would authorize the President to issue annually a proclamation urging the people of the United States to give heed to this significant medical problem and to cooperate in all steps for its solution The companion measure in the Senate, S J Res 35, was introduced by Senator Bridges, New Hampshire

A **veterans' hospital** at Taft, Okla , for Negro veterans would be authorized by H R 150, introduced by Representative Stigler, Oklahoma

Representative Davis, Tennessee, proposes by H R 227 to authorize the President to appoint as commissioned officers in the Medical Corps of the Army and the Medical Corps of the Navy, on the recommendation of the Surgeon General of the Army or Navy, as the case may be, **x-ray technicians** who are regularly registered to practice as such in any state or in the District of Columbia

A bill introduced by Representative Kelley, Pennsylvania, H R 254, would authorize the director of the Office of Vocational Rehabilitation to encourage, foster and assist in the development, establishment and maintenance of special services and facilities for **handicapped persons**

A United States Commission on **Physical Fitness** would be established under the provisions of H R 220, introduced by Representative Buchanan, Pennsylvania, to promote the physical fitness of the inhabitants of the United States through physical training and competition in all athletic sports, camping and kindred activities For the first fiscal year an appropriation of $25,000,000 would be authorized and thereafter such sum as the commission may recommend and the Congress may determine

STATE LEGISLATION

California

Bills Introduced—A 229 proposes that the **testing of the sight and hearing of school children** be mandatory rather than permissive A 256, to amend the **workmen's compensation act,** proposes to prohibit any company from contracting with any physician hospital or other person for the medical or surgical care or hospitalization *of any injured employee on the basis of such physician,* hospital or other person receiving a percentage of the gross premiums collected by an insurance company or on the basis of any percentage of the employer's payroll or on the basis of any fixed charges which are less than the rates adopted by the industrial accident commission The proposal would further prohibit a physician, hospital or other person from paying over to any employer or insurance carrier a rebate for any sums received for the medical or surgical care or hospitalization of an injured employee A 330, to amend the **chiropractic act,** *proposes that total or partial* blindness shall not be a disqualification for a license to practice chiropractic nor shall any person otherwise qualified be denied the right to file an examination for such license because he is blind A 359 proposes to include chiropodists within the meaning of the term "physician" as used in the workmen's compensation act S 62, to amend the business and professions code, proposes the creation of a board of **naturopathic examiners.** Naturopathy is not defined, but the proposal would authorize the board to grant two forms of certificates (a) naturopathic physician's certificate and (b) minor surgery and obstetrics certificate The naturopathic physician's certificate would authorize the holder to diagnose and treat all human ailments and abnormalities by the use of such forces and substances as light, air, water, clay heat rest, diet, herbs, electricity, massage, Swedish movements, suggestive therapeutics, magnetism, physical culture and mental culture The minor surgery and obstetrics certificate would authorize the holder to practice obstetrics and minor surgery according to accepted procedures but would not authorize the penetration of the eyes, or the cranial thoracic or abdominal cavities of human beings, or the amputation of human arms, hands, fingers, legs, feet, or toes or the practice of plastic surgery

Delaware

Bills Introduced—H 42 proposes to require each applicant for a **marriage license** to obtain a certificate from a duly licensed physician showing that the applicant has undergone a standard serologic test for syphilis and is not infected with such disease S 76, to amend the law relating to the distribution of certain drugs and preparations, proposes that the sale of penicillin, the sulfonamides and thyroid, and preparations containing them may be sold or **dispensed only on prescription** of a duly licensed practicing physician, practicing dentist or practicing veterinarian

Maryland

Bills Introduced—H 52, to amend the **medical practice act,** proposes to exempt therefrom persons treating human ills in accordance with the tenets of Christian science H 69 proposes the creation of a **state board of physical therapy examiners** and defines physical therapy as "the treatment of human injuries, diseases or disabilities by means of the healing properties of massage ultraviolet rays, mechanical devices, heat, cold, air, light, water and electricity, but not by means of roentgen rays, radium, surgery or drugs " The proposal also states that a physical therapist is one who treats only patients diagnosed and referred by licensed medical doctors H 83, to amend the **chiropractic act,** proposes among other things, to define chiropractic as "diagnosis, the location of misalined or displaced vertebrae of the human spinal column, the procedure preparatory to and the adjustment by hand of such misalined or displaced vertebrae of the spinal column and its articulations, by any method not including the use of drugs, surgery or obstetrics, osteopathy, optometry or podiatry, or any branch of medicine for the purpose of relieving such interference and aiding in the restoration of health, provided that nothing herein contained shall be construed to prohibit the use of by any licensed chiropractor of all necessary electrical, mechanical, dietetic and sanitary measures incident to the care of the human body, for the purpose of relieving such interference "

North Dakota

Bill Introduced—S 38 proposes to require every physician, or other person authorized by law to practice obstetrics, who attends a pregnant woman for conditions relating to pregnancy, to take or cause to be taken a **sample of blood of such woman** at the time of the first professional visit and to submit such sample to an approved laboratory for a standard serologic test for syphilis

Tennessee

Bill Enacted—S 15 has become chapter 2 of the public acts of 1947 It repeals the **naturopathic practice act** of Tennessee and provides that it shall hereafter be unlawful for any person, whether heretofore licensed or not to practice naturopathy in the state

GOVERNMENT SERVICES

ARMY

DEEP X-RAY CENTERS FOR RESEARCH AND TREATMENT

The Army Medical Department still operates 4 deep x-ray centers where patients are treated for cancer—Walter Reed General Hospital, Washington, D. C.; Beaumont General Hospital, El Paso, Texas; Army and Navy Hospital, Hot Springs, Ark., and Letterman General Hospital, San Francisco. During the war cancer was not a major problem at any time, the highest incidence rate being 0.34 per 1,000 per year, or about 3 men of every 10,000. Walter Reed General Hospital has one of the few million volt roentgen therapy machines in the world, and it is as easy to operate as the 200 kilovolt x-ray machine seen in many hospitals. A tumor board which convenes at Walter Reed General Hospital every week consists of the chiefs of surgery, laboratory, pathology and radiation therapy services, who consider each case of cancer individually and recommend the type of treatment.

HISTORY OF THE 36th GENERAL HOSPITAL

A brief history of the 36th General Hospital, Wayne University, Detroit, sponsored unit, was recently distributed to personnel who served with that unit to commemorate the first anniversary of its deactivation. The history follows the unit through its three and one-half years in North Africa, Italy and France. The foreword is written by Dr. Richard M. McKean, who served as chief of medical service during most of the hospital's activities overseas and later became its commanding officer. Originally the history was written by two noncommissioned officers, George A. Cavanaugh and John D. Gall, who served with the unit. It was revised by Dr. McKean for the anniversary.

WIDOWS MAY CLAIM TERMINAL LEAVE PAY

The widows, children or parents of former soldiers who died after honorable discharge from the Army and who had not claimed their terminal leave pay prior to their death are entitled to collect these payments, the War Department has announced. Such survivors should write immediately to the Finance Officer, U. S. Army, Army Finance Center, Building 204, St. Louis 20, for application. Only a small number of claims of this type have been received thus far, but it is estimated that in all about 40 million dollars is due eligible survivors of army personnel in this category.

NEW DIRECTOR OF ARMY MEDICAL LIBRARY

Col. Joseph H. McNinch, M. C., has been designated director of the Army Medical Library, Washington, D. C., succeeding Col. Leon L. Gardner, M. C. Colonel McNinch during the war served on the staff of Major Gen. Paul Hawley in the European theater and since returning to the United States has been chief of the historical division in the Surgeon General's Office. He graduated from Ohio State University College of Medicine in 1930 and went directly into the medical corps of the Army. He was recently awarded the Legion of Merit.

COLONEL FREER RETIRES

Col. Arden Freer, M. C., chief of the medical consultants division, Surgeon General's Office, will retire from active duty in February after thirty-two years of service and will join the staff of the medical director of the Veterans Administration in Washington. Colonel Freer was chief of the medical service at Walter Reed General Hospital and director of the department of internal medicine at the Army Medical Center in Washington from 1939 to 1942. During World War I he served with the First Division. Recently he was awarded the Distinguished Service Medal for "exceptionally meritorious service."

NEW HEAD OF MEDICAL CONSULTANTS DIVISION

The War Department has announced that Col. Henry C. Dooling, M. C., former chief health officer, the Panama Canal Zone, has been named chief of the medical consultant's division in the Surgeon General's Office to succeed Col. Arden Freer, recently retired. Colonel Dooling, a native of New Jersey, who entered the Medical Corps during World War I, held the temporary rank of brigadier general during World War II and was awarded the Legion of Merit. Formerly he was chief medical service officer, Beaumont General Hospital, El Paso, Texas, and chief of medical services at Fort Riley station hospital, Kansas.

MEDICAL OFFICERS APPOINTED

The War Department recently announced the appointment to the regular Army of the following medical officers:

Major Schuyler P. Brown	Lincoln, Neb.
Major Sheldon S. Brownton	La Grande, Oregon
Major Anthony Czerwinski	St. Louis
Major John R. Darrah	Spokane, Wash.
Capt. Lindsay J. Ervin	Montrose, S. D.
Major Donald L. Ferris	Cos Cob, Conn.
Major Vincent L. Frankfurth	Spartanburg, S. C.
Major Patrick H. Hoey	Pittsburgh
Capt. George M. Knauf	Rising Sun, Md.
Capt. George H. Kojac	New York
Major Clarence B. La Dine	Indianapolis
Capt. Robert A. McLane Jr.	Phoenix, Ariz.
Capt. Robert E. Nuernberger	Wakefield, Neb.
Major Harold D. Parks	Randolph Field, Texas
Major Albert D. Phillips	Sacramento, Calif.
Capt. Bradley W. Prior	Buffalo
Lieut. Charles O. Rixey	Washington, D. C.
Major John A. Schindler	East Ann Arbor, Mich.
Capt. Max L. Smith	Los Angeles

PERSONALS

Brig. Gen. Guy B. Denit has been appointed chairman of a legislative committee established to examine all current legislative proposals affecting the Medical portion of the War Department's legislative program. The committee will prepare a legislative program for the future needs of the Medical Department and will prepare data in support of, or in opposition to, current legislative proposals affecting the Medical Department.

Col. Frank L. Cole, M. C., director of the surgical consultant division, Surgeon General's Office, was recently elected a member of the board of governors of the American College of Surgeons.

Col. Wesley C. Cox, M. C., has been assigned as the new chief of the Army Industrial Hygiene Laboratory at Edgewood Arsenal, Maryland, with offices in the Surgeon General's Office. Colonel Cox recently returned from service in Panama, where he was Canal Department surgeon. At one time he was an instructor in bacteriology and preventive medicine at the Army Medical School, and Chief, 8th Corps Area Laboratory, Fort Sam Houston, Texas.

Col. Tom F. Whayne, M. C., has been appointed president of a board which will develop the medical portion of the War Department's program for aid to civilian populations in liberated countries.

ARMY AWARDS AND COMMENDATIONS

Colonel James B. Anderson

The Legion of Merit was recently awarded to Col. James B. Anderson, M. C., U. S. Army, of Bradenton, Fla., who was the commanding officer of Ashburn General Hospital, McKinney, Texas, from February 1943 to October 1945, where, states the citation, "he rendered outstanding service and demonstrated unusual clinical ability and administrative skill in setting up and maintaining high standards in the care of patients. His meticulous attention to details and thorough knowledge of hospital work enabled him to suggest and have embodied many improvements in his hospital while it was under construction. Through his keen observation, mature judgment and signal ability to evaluate his personnel and their capabilities, he was able to assign them to positions where they could be of maximum benefit to the service and receive training preparing them for proficient service in overseas theaters. Colonel Anderson displayed indefatigable leadership, penetrating insight and loyal devotion to duty in organizing the Arthritic Center of Ashburn General Hospital at a high level of efficiency. His achievements contributed materially to the war effort, reflecting highest credit on himself and the military service. Dr. Anderson graduated from the Medical College of Virginia, Richmond, and entered the service Jan. 8, 1918.

Colonel Robert A. Trumbull

The Legion of Merit has been awarded to Col. Robert A. Trumbull, M. C., A. U. S., of Dallas, Texas, who as chief, personnel section, office of the surgeon, headquarters, Army Air Forces Training Command, during the period from May 1942 to September 1945, rendered valuable medical contributions by exhibiting great professional skill, sound judgment and an unusual ability to solve the multitudinous problems which confronted his department. The citation also stated that, assisting substantially in maintaining a superior level of professional care and in rendering distinguished services to the health of Army Air Forces Training Command personnel, Colonel Trumbull performed a service which reflects great credit on himself and the armed forces of the United States. Dr. Trumbull graduated from the Medical Department of Southern Methodist University, Dallas, Texas, in 1913 and entered the military service in May 1942.

Lieutenant Colonel Harold R. Hennessy

Lieut. Col. Harold R. Hennessy, M. C., A. U. S., formerly of Berkeley, Calif., was recently awarded the Bronze Star Medal, the citation calling attention to his meritorious service in connection with military operations against the enemy of the United States during the period April 2, 1945 to May 8, 1945 in Belgium and Germany. As public health officer in the office of the army surgeon, Lieutenant Colonel Hennessy demonstrated outstanding qualities of leadership by organizing and directing the public health control of displaced persons, refugees and the German civil population in the Rhineprovinz military district. Through his personal efforts the spread of typhus throughout the army area was halted in a remarkably short time, thus averting a critical problem. Colonel Hennessy's reliability, aggressiveness and tactful nature reflect great credit on himself and the armed forces of the United States. Dr. Hennessy graduated from the University of Minnesota Medical School, Minneapolis, and entered the service Feb. 21, 1943.

Lieutenant Colonel Frank P. Guidotti

The Legion of Merit was recently awarded to Lieut. Col. Frank P. Guidotti, M. C., A. U. S., of New York for performing exceptionally meritorious service in the Second Service Command from March 1942 to October 1945. The citation mentioned especially his work as chief medical examiner of the induction station, New York City, where his planning and reorganization of operating procedures resulted in saving considerable sums of money for the government and likewise conserved manpower by reducing operating personnel during a critical period. He contributed materially to the planning and the development of the medical facilities at the Army's Ground and Service Forces Redistribution Stations, Lake Placid, N. Y., and Atlantic City, N. J., and the separation centers in Fort Dix and Fort Monmouth, which also resulted in a saving of expense to the government. Dr. Guidotti, who graduated from the Regia Università di Napoli Facoltà di Medicina e Chirurgia, entered the service Oct. 8, 1940.

Lieutenant Colonel Francis B. Carroll

The Legion of Merit was recently awarded to Lieut. Col. Francis B. Carroll of Great Barrington, Mass., who distinguished himself in the performance of outstanding service as epidemiologist and chief, Preventive Medicine Branch, Office of the Surgeon, First Service Command, from June 1943 to October 1945. By his sound judgment, wide professional knowledge and meticulous efforts, states the citation, he organized and supervised a program of preventive medicine which was entirely responsible for the low incidence of epidemic and contagious disease within the Service Command. His investigation during an outbreak of meningococcic meningitis resulted in obtaining scientific information in the use of sulfadiazine to control the spread of this disease and was of inestimable value in preventing its spread throughout the armed forces. He conducted pioneer studies in the determination of the degree and rate of rise in immunity produced by inoculations with diphtheria and tetanus toxoid, and his observations brought about many improved methods of immunization. Dr. Carroll graduated from the University of Rochester School of Medicine and Dentistry in 1935 and entered the service Feb. 10, 1943.

Lieutenant Colonel James J. Callahan

The Legion of Merit was recently awarded to Lieut. Col. James J. Callahan, M. C., A. U. S., of Oak Park, Ill., who, as consultant in orthopedic surgery, Fourth Service Command, from June 1944 to August 1945 performed a diversity of tasks. The citation referred especially to the fact that in the face of unprecedented expansion of orthopedic service within the command he formulated and carried into effect the entire program, simultaneously maintaining an exceptionally high standard of treatment for thousands of orthopedic cases. He organized, staffed and secured supplies for brace shops at all general and regional hospitals and supervised training of orthopedic mechanics. He guided experimental work on combat boots at Fort Benning, Georgia, and his services were of inestimable value in determining the correct type of combat boot to be worn by the foot soldier. Dr. Callahan graduated from Loyola University School of Medicine, Chicago, in 1928 and entered the service Nov. 5, 1943.

Major Hugh W. Savage

The Legion of Merit was recently awarded to Major Hugh W. Savage, M. C., A. U. S., of Fort Worth, Texas, who as chief, Domestic Air Evacuation, and as commanding officer, 830 Medical Air Evacuation Squadron, Air Transport Command, from May 1944 to December 1945, was responsible for the foresighted and thorough planning of the safe and expeditious system for returning casualties to the United States. The citation says that his resourcefulness, ingenuity and unstinting devotion to duty reflect great credit on himself and the armed forces of the United States. Dr. Savage graduated from the University of Arkansas School of Medicine in 1941 and entered the service July 1, 1942.

Captain Alfred R. Wollack

The Soldier's Medal has been awarded to Capt. Alfred R. Wollack, M. C., A. U. S., of Park Ridge, N. J., who on Dec. 21, 1945 aboard the S. S. *Athos II* made his way across its hurricane engulfed deck to administer first aid to military personnel injured by forces of the storm. The citation described how his calm procedure under difficult conditions greatly improved the comfort and morale of passengers and was indicative of heroism in the highest degree. Dr. Wollack graduated from New York University College of Medicine in 1942 and went on active duty in the Army in July 1943. He has been awarded also the Bronze Star Medal with Oak Leaf Cluster.

Captain William A. Byrne

The Bronze Star was recently awarded to Capt. William A. Byrne, M. C, A. U. S., of Seneca Falls, N. Y., "for meritorious achievement in connection with military operations against the enemy from Dec. 16, 1944 to Jan. 8, 1945 in Luxembourg and Belgium Throughout this period," the citation disclosed, "Captain Byrne directed the operation of his casualty clearing station in a most efficient and exemplary manner. Although under heavy enemy shell fire he fearlessly went about coordinating the work of his station and maintained an efficient evacuation system When his station became handicapped by a shortage of medical officers and heavy casualties, he worked tirelessly for long hours treating the wounded. The outstanding devotion to duty, ceaseless energy and professional skill displayed by Captain Byrnes reflects great credit on himself and are in keeping with the highest traditions of the military service." Dr. Byrne graduated from Hahnemann Medical College in 1943 and entered the service Jan. 7, 1944.

NAVY

RESERVE OFFICERS WANTED FOR ACTIVE DUTY

Reserve Medical Officers and Pharmacists now have an opportunity to return to active duty at one of the major naval air stations of the Naval Air Reserve Training Command or at one of the Naval Air Reserve Training Units. Reserve officers and pharmacists who are interested should initiate letters to the Bureau of Naval Personnel through the Chief of Naval Air Reserve Training, Naval Air Station, Glenview, Ill., listing three or four stations at which duty is desired in order for preference. Personnel are desired not above the rank of Commander in the Medical Corps. Government quarters are available at many of the major naval air stations. Some of these billets carry orders to duty involving flying for designated Naval Flight Surgeons.

ADDRESS BY DR. J. B. S. HALDANE

The fourth in a series of lectures at the Naval Medical Center, Bethesda, Md., was delivered January 9 by Dr. J. B. S. Haldane, professor of biometry, University College, London, England. Officers of the Army and Navy Medical Corps, Public Health and Veterans Administration and civilian doctors of the District of Columbia and Montgomery County were invited to attend the lecture, after which refreshments were served. Dr. Haldane has continued the work of his late father, the scientist J. S. Haldane, who was a foremost authority on respiration.

SCHOOL OF TROPICAL MEDICINE IN GUAM

At the opening of the new Naval School of Tropical Medicine in Guam Sept. 31, 1946 the speakers were Dr. Victor G. Heiser, Rear Admiral H. W. Smith, Ret., Capt L. B. Marshall, M. C., in command of the new Naval Medical Center, of which the Institute of Tropical Medicine is a unit, Commodore W. E. Kellum, M. C., from Pearl Harbor, fleet medical officer, Comdr. S. A. Britten, M. C., who spoke on tuberculosis in native populations, Capt E. H. Hudson, M. C, on yaws, and Capt. J. J. Sapero, M. C., on malaria The School of Tropical Medicine is under the direction of Comdr. F. A. Butler, M. C. The first class at the school comprised sixteen medical officers, who subsequently will be assigned to military duties throughout the Pacific area.

VETERANS ADMINISTRATION

HOME TOWN MEDICAL CARE FOR VETERANS

Veterans with service incurred disabilities in 32 states, Hawaii and the District of Columbia may obtain free medical treatment from physicians of their choice under two different plans of the Veterans Administration home town medical care program. Both plans enable veterans with service incurred or service aggravated ailments, on approval of their Veterans Administration medical officer, to go to the local physician of their choice for treatment of that service connected ailment only. About half the states are operating under the so-called Michigan plan, the others under the so-called Kansas plan

Under the Michigan plan a nonprofit organization or corporation sponsored by the state medical society handles the administrative details for the Veterans Administration, including the payment of cooperating physicians. The Veterans Administration in turn, pays the organization a lump sum for the professional services rendered, plus a small additional amount for handling the administrative work Under the so-called Kansas plan all administrative work, including payment of individual doctors, is taken care of by the Veterans Administration, and there is no go between organization. Under both plans state medical organizations serve constantly to see that veterans are at all times getting the best possible medical attention.

The following medical organizations are cooperating with the Veterans Administration under the so-called Michigan plan:

California Physicians Service, Los Angeles
Colorado Medical Service, Inc, Denver
Hawaii Medical Service Association, Honolulu
Associated Hospital Service of Maine, Portland
Michigan Medical Service, Detroit
Montana Physicians Service, Helena
The Hospital Saving Association of North Carolina, Inc, Chapel Hill
Oregon Physicians Service, Portland
South Dakota State Medical Association, Sioux Falls
Hospital Benefit Association of South Carolina, Greenville
Minnesota State Medical Association, St. Paul
Washington State Medical Bureau, Seattle
Iowa Medical Service, Des Moines
Wisconsin Veterans Medical Service Agency, Madison
Medical Service Administration of New Jersey, Newark
Veterans Medical Service Plan of New York, New York
North Dakota State Medical Association, Williston

The following medical groups are cooperating with the Veterans Administration under the so-called Kansas plan:

Florida Medical Association, Jacksonville
Wyoming State Medical Society, Casper
Louisiana State Medical Society, New Orleans
Arkansas Medical Society, Fort Smith
Connecticut State Medical Society, New Haven
Medical Society of the District of Columbia, Washington
Medical Association of Georgia, Atlanta
The Illinois State Medical Society, Monmouth
Idaho State Medical Association, Lewiston
Indiana State Medical Association, Indianapolis
Kansas State Medical Society, Wichita
Ohio State Medical Society, Cincinnati
The Medical Society of the State of Pennsylvania, Pittsburgh
Medical Service Bureau of the Utah State Medical Association, Salt Lake City
West Virginia State Medical Association, Charleston
Nevada State Medical Association, Reno
Tennessee State Medical Association, Memphis

HOSPITAL NEWS

The army engineers have let the architect-engineer contract for the Veterans Administration hospital at Erie, Pa., which will be a 200 bed general medical and surgical hospital.

President Truman has approved the purchase of 18 acres of land on University Avenue in West Philadelphia, Pa, as a site for a 1,000 bed Veterans Administration hospital adjoining the Philadelphia General Hospital and the University of Pennsylvania School of Medicine. The President has also approved sites in Olmstead Park in Boston and in Syracuse, N. Y., for 1,000 bed veterans' hospitals. The Syracuse project will involve the removal of an abandoned cemetery and the reinterment of some 4,500 bodies in a new location. This hospital will be built on the 11½ acres adjoining Syracuse University Medical School.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Bulletin on Monthly Basis.—Beginning January 3 the *Bulletin* of the San Diego County Medical Society went on a monthly basis rather than biweekly. It is expected that the publication will be enlarged. Dr. William H. Gerstweit Jr., San Diego, is the editor.

Personal.—Dr. Otto Guttentag, University of California Medical School, Berkeley-San Francisco, has been granted a temporary leave of absence in order to fill his appointment as consultant on medical education in Germany with the office of the military government in Germany.——Dr. Charles Calhoun Hedges, Vallejo, former health officer of Kings County, has been appointed health officer of Tulare County. A graduate of the University of Virginia, he held full time county health offices in Virginia and West Virginia before coming to California in 1943.

Conference on Alcoholism.—Alcoholism as a public health problem will be the subject for discussion at a conference of physicians, psychiatrists and social workers February 12 in Rodger Young Auditorium, Los Angeles. The conference, sponsored by the Welfare Council, Southern California Society for Mental Hygiene and individual members of Alcoholics Anonymous, Inc., is planned as an aid to alcoholic addicts through the use of medical science, education and understanding. On the program will be Dr. Anton J. Carlson, president and scientific director of the Research Council on Problems of Alcohol; Joseph Hirsh, associate director of the Research Council; Drs. Karl M. Bowman, San Francisco; Lawrence Kolb and Mrs. Dora Shaw Heffner, State Department of Mental Hygiene, Sacramento, and Richard McGee, director of Corrections, California.

CONNECTICUT

Resigns from Medical Examiners Board.—Dr. John C. Rowley, Hartford, a member of the Connecticut Board of Medical Examiners since 1916, declined reappointment to the board December 31. Dr. Wilmet C. Townsend, Hartford, was appointed for a five year term beginning January 1. Dr. Townsend received his degree in medicine from Harvard Medical School, 1925. He has been engaged in the practice of internal medicine and is attending physician at Harvard Hospital. He served in the medical corps, A. U. S., from September 1942 until January 1946, when he was discharged as a lieutenant colonel.

Yale Receives Klebs Library of Medical History.—After a delay of almost four years the extensive medical library of the late Dr. Arnold C. Klebs, Nyon, Switzerland, has been delivered to the Yale Medical Library in New Haven. Before his death in March 1943 Dr. Klebs, although not a Yale man, was persuaded by the late Dr. Harvey Cushing, Yale 1891, to deed his collections to Yale University. His library of more than 22,000 titles was carefully packed under the supervision of Dr. A. C. Breycha-Vauthier, deputy librarian for the United Nations Library, and stored for the duration of the war at Geneva, Switzerland. The arrival of the Klebs gift marks the fulfilment of Dr. Cushing's original idea of bringing together at Yale his own books on the history of medicine together with the collections formed by his intimate friends, Drs. Klebs and John F. Fulton, Sterling professor of physiology, Yale University School of Medicine.

ILLINOIS

Seventeen Counties Vote for County Health Departments.—Seventeen counties have been added to the list of five others in Illinois which have established locally financed and administered county health departments. The Illinois State Department of Public Health and the Illinois Statewide Health Committee have been working since 1942 for full coverage of the state by full time provisional staff health departments in cities and counties. Of the one hundred and two counties in Illinois, twenty-two are in a position to profit by the type of public health protection which two thirds of the other counties in the United States enjoy, it is reported. In the November election one four-county and three bi-county health departments were authorized.

Chicago

Public Health Institute Closes Its Doors.—The Public Health Institute, a nonprofit clinic for the treatment of venereal diseases founded in 1920 and for many years located at 159 North Dearborn Street, according to the Chicago *Tribune*, has closed its doors. The assets, which are said to be comparatively small, will be given to Northwestern University to establish a fund for the treatment and study of venereal disease and other public health problems. The institute from the beginning had been sponsored by a group of well known business men. The *Tribune* also points out that an increase in reported venereal diseases has occurred in Chicago. For the year ended June 30, 1946 the number of cases is said to have totaled 42,097 compared with 29,119 for 1942-1943. The number of cases of gonorrhea reported is said to have increased from 12,000 in 1942 to 25,000 in 1945.

Symposium on Medicolegal Problems.—Under the sponsorship of the Institute of Medicine of Chicago, the Chicago Medical Society and the Chicago Bar Association, a series of five meetings have been scheduled for Tuesday evenings beginning February 4 and extending through March 4. Meetings will be held at the Chicago Bar Association, 29 South La Salle Street. "Psychiatry and Civil Law" is the subject of the first meeting, February 4, with James F. Oates Jr., president, Chicago Bar Association, presiding. The medical presentation will be made by Dr. Francis J. Gerty, professor of psychiatry and head of the department, University of Illinois College of Medicine. The honorable Harry M. Fisher, judge of the circuit court of Cook County, will give the legal presentation. On February 11 "Psychiatry and Criminal Law" will be discussed with Dr. George F. Lull, Secretary and General Manager, American Medical Association, presiding. Dr. Paul L. Schroeder, professor of criminology and head of the Institute for Juvenile Research, University of Illinois College of Medicine, and William F. Crowley, first assistant state's attorney, Cook County, will give the medical and legal presentations. The third subject of the symposium to be presented February 18 is "The Skeleton Speaks: Medical and Legal Implications" with Werner W. Schroeder, Esq., of the Chicago Bar Association, presiding. Wilton M. Krogman, Ph.D., associate professor of anatomy and physical anthropology, University of Chicago, and A. R. Peterson, Esq., of the Chicago Bar Association, will make the presentations. The remainder of the program will be announced in a later issue.

Report on Sunshine, Smoke and Dust.—The U. S. Public Health Service made a study of air pollution in Chicago as a part of a survey of health conditions requested by the city and county governments. The report referred to the surveys on dust which have been made for many years. Each month analyses of dust fall precipitation is still being made at twenty-two stations in Chicago. The monthly average per square mile of dust fall for the year 1945 varied from 212.10 tons at 33 North La Salle Street to 24.06 tons at 7350 Pratt Boulevard. The average monthly dust fall per station was 68.40 tons per square mile, and this was a decided improvement, as shown by the records of twenty years ago. The control of air pollution, the report says, is difficult. About 1,200 locomotives, 25 roundhouses, 450 steamship arrivals per season, 400,000 buildings and other miscellaneous items contribute to the smoke problem. The U. S. Weather Bureau reported that in 1945 Chicago received only 56 per cent of the possible hours of sunshine. Smoke alone is not responsible for this percentage but, combined with fog and partial cloudiness, is a factor in the sunshine record. Chicago has a department of smoke abatement, but the appropriation for this department in 1946 failed to provide adequate personnel to observe all smoke violations and nuisances in the department's seven districts. The report recommended that the Cook County Commission conduct a survey with a view to establishing rules and regulations for smoke abatement and control of air pollution, and that the industrial communities in Indiana near Chicago—Hammond, Whiting, Gary, Indianapolis, Indiana Harbor and East Chicago—be urged to adopt effective legislation for smoke abatement and air pollution control. The railroads, it is estimated, account for about 25 per cent of the city's smoke.

MICHIGAN

Oakland County Deputizes Coroners.—Under a special legislative act, Oakland County now deputizes private physicians to act as coroners when needed. Heretofore they have been elected. Under the new setup doctors will be paid $7 for each call plus mileage. They may be summoned by the county health department or the police. Economy as well as efficiency is the goal of the new system.

Diagnostic Centers for Rheumatic Fever.—The Michigan State Medical Society has established diagnostic centers for rehumatic fever in nine cities throughout the state—Lansing, Grand Rapids, Kalamazoo, Bay City, Traverse City, Jackson, Ann Arbor, Flint and Marquette. Family doctors are invited to bring cases to these centers for diagnosis, laboratory tests and consultation. Clinics were established when the society learned that many Michigan youths were rejected from military service because of cardiac trouble due largely to rheumatic fever.

Typhoid Carriers in Michigan.—For the past thirteen years not 1 case of typhoid has been traceable to a public water supply in Michigan, according to the department of health. The only source of the disease now is carriers, the number of which has decreased from 288 to 262 in 1946. All known typhoid carriers are registered with the health department and visited four times each year by state or local health officials to be sure that they are not employed to handle food or to work in water treatment plants. Eighty-eight cases of typhoid were reported in the state during 1946, as compared to 5,122 in 1900.

MISSISSIPPI

Legislature Grants Out of State Scholarship Loans.—Mississippi is the first state to grant scholarship loans to its young men and women to be used to study medicine in various other schools throughout the nation. The Mississippi State Medical Education Board recently granted forty-seven such scholarships. The University of Mississippi School of Medicine, the only medical school in the state, offers courses in the basic medical sciences but offers no clinical work. West Virginia offers its residents outstate medical scholarships for study in Virginia only.

NEW JERSEY

Certificates of Appreciation.—At a ceremony in Newark, November 20, Certificates of Appreciation from the War Department were presented to ten New Jersey physicians, each of whom had served continuously for three or more years on the Induction Examining Board in the New Jersey-Delaware Recruiting and Induction District. The certificates were signed by Secretary of War Robert P. Patterson and Major Gen. James A. Van Fleet, commanding the Second Service Command. In the citations the War Department expressed its appreciation for patriotic service in a position of trust and responsibility to Herbert R. Van Ness as coordinator of activities of all civilian physicians and as a member of the surgical staff, to George T. Banker as chief of the internal medicine department, to James G. Enright as a member of the internal medicine department, to Isaac E. Gluckman as a member of the internal medicine department, to Nicholas W. Sivolella as a member of the internal medicine department, to Edward A. Murphy as head of the ophthalmologic department, to Jacob Piller as chief of orthopedic surgery, to Samuel Orloff as a member of the pathologic department, to William J. Donahue as a member of the psychiatric department and to Solomon J. Lurie as a member of the surgical staff.

NEW YORK

Speakers' Service.—A survey is now being conducted by the Medical Society of the State of New York to look into the possibility of setting up a speakers' service and to see how this may best be brought about. A member of the staff of the state society is conferring with officials of county societies to learn their present activities and future needs.

Research into Causes of Chronic Alcoholism.—Cornell University Medical School will undertake a five year research project into the causes of chronic alcoholism. It is being financed by funds from the Research Council on Problems of Alcohol and several distilling companies, together with sources of the school and hospital funds. The research is to be carried on under the direction of Dr. Oscar Diethelm, professor of psychiatry at Cornell and psychiatrist in chief at the hospital. The project is in effect a continuation of work that a research team at the hospital has been carrying on for the past five years.

Personal.—Fred Karush, Ph.D., Elmhurst, has been awarded a three year senior fellowship by the American Cancer Society for research at New York University College of Medicine under the direction of R. Keith Cannan, D.Sc., department of chemistry. Mr. Karush has been with the Du Pont Chemical Company for five years following his graduation from the University of Chicago in 1938.——Dr. Louis E. Marshall, Brooklyn, who was recently separated from the army with the rank of lieutenant colonel after five and a half years of service, has been appointed director of laboratories at the House of the Good Samaritan Hospital, Watertown, effective January 1.

State Aid for Health Program.—A new state health program began on January 1 under an increase of $8,000,000 in state aid to New York City in 1947 and an increase of $2,090,000 for up state communities, according to budget estimates of the state health department. The program was provided last spring by the state legislature for accelerating the control of tuberculosis, stimulating the establishment of more county health departments and improving city health services. The increase in state aid, it is reported, has already resulted in the establishment of four county health districts in addition to six previously established. The state will pay one half the cost, not to exceed $2.50 a day, of providing hospital care for tuberculosis patients and one half the cost of public health programs approved by municipal health departments. It is expected that equality of treatment on both a qualitative and quantitative basis will be established throughout the state as soon as minimum standards for hospital care are established.

New York City

New Center for Cerebral Palsy.—The Cerebral Palsy Treatment and Training Center, 150th Street and St. Nicholas Place, opened January 17, the first such center in the metropolitan area. Sponsored by the Pediatric Foundation, the center will have a staff of physicians and therapists who will examine and treat cases and seek their causes. This establishment follows studies by the State Joint Legislative Committee on Cerebral Palsy.

Home Care for Cancer Patients.—Montefiore Hospital has instituted a project to test whether advanced cancer patients can be allowed to remain at home and at the same time be provided with the equivalent of hospital care. Patients will be provided with several visits a week by doctors from the hospital staff, daily nursing care by a visiting nurse, transportation to and from the dispensary and help with housework when necessary. The New York City Cancer Committee has given $30,000 in aid. It is estimated that home care will be one-third to one-half the cost of comparable care in the hospital. Dr. Ephraim M. Bluestone is director of the hospital.

Celebrate One Hundred and Twenty-Fifth Anniversary.—The Medical Society of the County of Kings and Academy of Medicine of Brooklyn will be 125 years old during 1947. The society began the celebration of the anniversary at a dinner honoring Dr. Thurman B. Givan, retiring president, at the Hotel St. George, Brooklyn, January 29. Dr. Morris Fishbein, Chicago, Editor of The Journal, spoke, as well as other medical and civic leaders. The society was organized in 1822 at a meeting in the home of Dr. Adrian Vandervcer in Flatbush. It established in 1844 now the oldest public medical library in the country and the only public medical library on Long Island, and built its own building in 1900.

Personal.—Dr. Edward C. Reifenstein Jr., formerly Harvard Medical School research fellow at the Massachusetts General Hospital, Boston, has been appointed research consultant to the Sloan-Kettering Institute for Cancer Research at the Memorial Hospital Cancer Center and also clinical research consultant to Ayerst, McKenna and Harrison, Ltd. He will carry on clinical research on the relation of glandular disturbances of cancer.——Dr. I. Newton Kugelmass has been appointed consultant nutritionist to the department of health and the department of hospitals, New York City.——Dr. Aaron Edwin Margulis has been appointed professor of bacteriology and director of the hospital and dispensary services of bacteriology in the New York Post-Graduate Medical School and Hospital, Columbia University, to succeed Dr. Ward J. MacNeal, deceased.

NORTH CAROLINA

Appointments at University of North Carolina.—The following professors have been added to the faculty of the University of North Carolina School of Medicine: Dr. Kenneth M. Brinkhous, formerly of the State University of Iowa College of Medicine, Iowa City; Dr. John B. Graham, instructor of pathology and resident of Cornell Medical Center, New York; Dr. William S. Randall, instructor in pathology and director of the pathological laboratory at Watts Hospital, Durham, N. C., and former chief of the laboratory, Walter Reed General Hospital, Washington, D. C.; Arthur V. Jensen, Ph.D., assistant professor of anatomy in charge of neuroanatomy, former research assistant at the Institute of Neurology, Northwestern University School of Medicine, Chicago; Fred L. Rights, assistant professor of bacteriology, formerly of the department of bacteriology, Columbia University College of Physicians and Surgeons; Dr. Frederick A. Blount, Pensacola, Fla., instructor in pharmacology, graduate of the University of Pennsylvania School of Medicine, Philadelphia, and Dr. John B. Riggsbee, instructor in anatomy, graduate of Vanderbilt University School of Medicine, Nashville, Tenn.

OHIO

Cleveland Diabetes Society.—At a meeting Dec. 9, 1946 the Cleveland Diabetes Society was formed under the leadership of Drs. Henry J. John, president, and Max Miller, secretary-treasurer. The society is patterned after the societies in New York and Philadelphia, and affiliation with the national association is planned.

Kelleys Island Needs a Doctor.—A house, office and $3,000 a year plus fees is being offered by the village of Kelleys Island to a physician who will practice in that community of some 500 residents located in Lake Erie not far from Sandusky. Following the disruption of telephone communications some time ago as the result of broken cables, emergency radio communication was established with the mainland. The Toledo *Blade* of January 3 stated that Kelleys Island was still without "an emergency doctor" despite appeals to various state organizations.

Aid to Preventive Medicine Department.—A $70,000 grant from the Cleveland Foundation has been made to Western Reserve University to aid in the operation of the Elisabeth Severance Prentiss department of preventive medicine. Of the total, $25,000 is to be paid immediately and the remainder in the amount of $15,000 a year for the next three years. The department of preventive medicine was created in 1945 by a gift of $606,000 from the estate of the late Mrs. Elisabeth Severance Prentiss, Cleveland. In addition to laying plans for cooperation with the community in a program of preventive medicine, the department is organizing and equiping a large laboratory to carry on research in infectious diseases. Hundreds of specimens of viruses and cultures obtained by the staff members while in military service will be available for experimental work.

PENNSYLVANIA

Rheumatic Heart Clinics Established.—The fifth Rheumatic Heart Clinic established in 1946 by the Pennsylvania Department of Health was opened recently in the Harrisburg Polyclinic Hospital. Its purpose is to register all patients under the age of 21 in Harrisburg and vicinity who are afflicted with rheumatic fever or rheumatic heart disease in order to develop an organized plan for diagnosis and treatment. Dr. Allen W. Cowley, Harrisburg, is director of the new clinic. The other four clinics are located in Altoona, Erie, Allentown and Williamsport.

UTAH

Western Society for Clinical Research.—At a recent meeting in San Francisco a new scientific medical society was launched with the purpose of providing annual meetings and discussions for investigators in clinical medicine and its allied fields. The meetings of this Western Society for Clinical Research are to fill the needs for scientific interchange of the West in a manner similar to those of the Central Society for Clinical Research in the Middle West and the Society for Clinical Investigation in the East. Two of the six counselors who were elected at the San Francisco meeting are members of the University of Utah School of Medicine, Salt Lake City: Drs. Charles E. McLennan, professor and head of the department of obstetrics and gynecology, and Hans H. Hecht, assistant professor, department of medicine. Dr. B. Valdemar Jager of the department of medicine reported on his study of the treatment and metabolic changes of certain types of arthritis, and Dr. Hecht presented the results of his and his associates' work on a new agent employed in the diagnosis and treatment of cardiovascular diseases.

WASHINGTON

University Organizes Clinical Departments.—Organization of clinical departments in the new University of Washington School of Medicine, Seattle, is being conducted by Dr. Edward L. Turner, dean. Dr. Henry N. Harkins, associate professor of surgery, has been appointed professor of surgery and executive officer of the department. It is anticipated that Dr. Harkins will assume his new duties about July 1. Others appointed as clinical professors of medicine are Drs. Edwin George Bannick, now chief of staff, Swedish Hospital, Seattle; Edwin S. Bennett, associate clinical professor, University of Southern California School of Medicine; Byron F. Francis, former medical director of Riverton Hospital for Chest Diseases, Seattle; Lester J. Palmer, member of the staff of Virginia Mason Hospital, Seattle, and Charles Edward Watts, consultant in medicine at the U. S. Marine Hospital, Seattle. Roscoe L. Pullen, formerly of Tulane University, New Orleans, has been appointed associate professor of medicine and director of hospital planning.

ALASKA

Personal.—Dr. Elaine A. Schwinge, Georgetown, S. C., has been appointed junior field physician for the Territorial Department of Health of Alaska.——The territorial health department has announced the resignation of Dr. N. Berneta Block, Juneau, as director of the division of maternal and child health and crippled children's services.

Sitka to Get New Orthopedic Hospital.—Approval has been granted by the Office of Indian Affairs, Washington, D. C., for a 50 bed orthopedic hospital at Sitka. A plan has been worked out for development of orthopedic facilities in the territory on a cooperative basis using the navy dispensary on Japanski Island at Sitka for facilities. Administration of the staff for the new hospital will be under the Alaska Native Service, and the hospital equipment and supplies will be installed and used on a loan basis from the territorial department of health, which will also supply technical personnel for the treatment of orthopedic cases on a consultant basis. Dr. C. Earl Albrecht, Juneau, health commissioner of Alaska, said 400 orthopedic cases, three fourths of them Indian, Eskimo and Aleut children, are now on the territorial roster.

PUERTO RICO

Laboratory to Make Vaccines.—The chief of the Bureau of Public Health of the Health Department of Puerto Rico, Dr. Oscar Costa-Mandry, announces that a new public health laboratory will be established near San Juan for the manufacture of vaccines and other products used by the department of public health. Dr. Costa-Mandry recently returned from the United States, where he made a survey of leading public health laboratories.

Membership in the Blue Cross.—More than 8,000 Puerto Ricans enrolled under the Blue Cross Hospitalization Plan on the island during the third quarter of 1946, according to official reports, bringing the total membership to 31,215 men and women eligible for Blue Cross benefits. A sharp increase in membership registered during the final quarter was the result of legislation which went into effect authorizing the government of Puerto Rico to appropriate funds to extend Blue Cross benefits to all government employees.

Proposed Hospital Program.—The Planning Board of Puerto Rico in its 1947-1952 financial program recommends to the governor and the legislature a vast plan for the construction of new hospitals and improvements to existing hospitals. According to Public Law No. 725 passed by the 79th United States Congress, Puerto Rico is included in the federal aid program for construction and enlargement of private and government hospitals. Under this legislation Puerto Rico will receive an allocation of funds amounting to $12,150,000 during the next five years. However, the insular government and private interests running nonprofit institutions will have to contribute two dollars for each dollar contributed by the federal government. The planning board estimates that private institutions will use about 30 per cent of the federal funds. Therefore it recommends an overall allocation of insular funds amounting to $16,750,000 for the next six years, out of which $5,553,000 is already allocated by different enabling acts passed by the insular legislature during the past two years. If this comprehensive program is approved by the governor and the insular legislature during its session in February, the following benefits accrue to the people of Puerto Rico: 1. The bed capacity for general hospitals will be increased 50 per cent, which will thus provide 3.6 beds per thousand inhabitants by the year 1953. 2. The bed capacity of the insular charity hospitals, or district hospitals, would be increased 75 per cent, and the recommended policy of 1 bed for each thousand inhabitants would be reached for each municipality on the island. Puerto Rico has 77 municipalities and a population now of over 2,100,000 inhabitants. 3. The number of beds available in all the tuberculosis hospitals on the island would be doubled, and the goal fixed by the insular department of health of 1 bed in each tuberculosis hospital for each death due to this disease would be reached. 4. The hospital facilities for mental and nervous diseases would be increased 75 per cent. The overcrowded situation has brought serious problems to these hospitals in Puerto Rico.

GENERAL

American College of Radiology.—The American College of Radiology and the Philadelphia Roentgen Ray Society will conduct a postgraduate course in radiology March 3 through April 4 in Philadelphia. Some of the subjects to be studied are certain neoplastic and inflammatory diseases, carcinoma of the head and neck, dosage calculation and tumor sensitivity in radiation therapy, carcinoma of the breast, blood and hemopoietic diseases, carcinoma of the genital and urinary tract and malignant and nonmalignant diseases of the skin.

Positions Open for Research in Psychiatry.—Twelve positions for research in psychiatry and related fields at the Western State Psychiatric Institute and Clinic have been established. The institute is a teaching and research hospital of the Pennsylvania mental hospital system, training psychiatrists, social workers, psychologists, nurses, occupational therapists and others for hospital and private fields. For further information write Dr. Grosvenor B Pearson, O'Hara and DeSoto streets, Pittsburgh 13.

Electroencephalographers to Meet in Montreal.—The Eastern Association of Electroencephalographers (The Journal, January 11, p. 117) will hold a meeting February 21-23 in the Montreal Neurological Institute, Montreal. At the first afternoon scientific session Dr. Derek E. Denny-Brown, Boston, will review the fundamental principles in electromyography. Saturday, February 22, Dr. Herbert Jasper, Westmount, Que., will introduce a seminar discussion on "Technics, Terminology and Electroencephalographers."

Pharmaceutical Manufacturers' Award. — The Mayo Foundation for Medicine, Education and Research at the University of Minnesota lately received the annual award of the American Pharmaceutical Manufacturers Association for its contributions to public health through fundamental research in medical sciences Isaiah Bowman, Ph D., president of Johns Hopkins University, presented the parchment scroll to Dr. Donald C. Balfour, director of the foundation. The award, made annually on the recommendation of a scientific advisory board, was won last year by the Rockefeller Foundation.

Interne and Medical Students' Convention.—The twelfth annual convention of the Association of Internes and Medical Students met in Philadelphia, December 27-29. Among the speakers were Dr. Isaac Starr, dean, University of Pennsylvania School of Medicine; Dr. Pascal F. Lucchesi, director, Philadelphia General Hospital; Dr. I. S. Ravdin, professor of surgery, University of Pennsylvania School of Medicine; Dr. Edward Weiss, professor of clinical medicine, Temple University School of Medicine; Dr. Stuart Mudd, professor of bacteriology, University of Pennsylvania School of Medicine, and Dr. Milton Roemer, U. S. Public Health Service, Washington, D. C.

National Conference on Medical Service.—The twentieth annual meeting of the National Conference on Medical Service will open at the Palmer House, Chicago, Sunday, February 9, with registration at 9 o'clock.

9.30 Call to order and address of the president, Dr. Cleon A. Nafe, Indianapolis
9.50 Dr. Joseph S. Lawrence, Washington, D. C., The Eightieth Congress.
10.10 Dr. Herman E Hilleboe, U. S Public Health Service, Washington, D. C., The Operation of Public Law 725 The National Hospital Construction Act
10 40 Discussion.
11.00 Dr. Paul B. Magnuson, Veterans Administration, Washington, D. C., Veterans' Care: Where Do We Go From Here?
11.30 L S. Kleinschmidt, Chicago, Medical Cooperatives.
11.50 Thomas A. Hendricks, Chicago, Developments in the Council on Medical Service.
12.15 Luncheon—Speaker to be announced.
2 15 Open Forum: Moderator, Dr. Creighton Barker, New Haven, Conn.; speakers, Drs. Duncan W. Clark, associate dean, Long Island College of Medicine; Byrl R. Kirklin, secretary, Advisory Board for Medical Specialties, Rochester, Minn.; Leo G. Christian, vice chief of staff, St. Lawrence Hospital, Lansing, Mich.; Thomas P. Murdock, chief of staff, Meriden Hospital, Meriden, Conn.; subject, Modern Influences in Medical Practice: Undergraduate Medical Education, Trends Toward Specialization; General Practitioners in Hospitals; Hospital Staff Organization.

Lasker Awards in Planned Parenthood. — The third Annual Lasker Awards of the Planned Parenthood Federation of America were presented to Drs. Alan F. Guttmacher, Baltimore, and Abraham Stone, New York, January 25. The award, a medallion and $500, recognizes Dr. Stone's devotion of thirty years to clinical work, teaching and marriage counseling. He and his late wife gave New York City its first marriage counseling center, which has served as a model for those in other American communities. He also founded and edits the medical periodical devoted to this subject, *The Journal of Human Fertility*, and is director of the Margaret Sanger Research Bureau. Dr. Guttmacher received the award in recognition for his successful work in gaining the support of physicians, the clergy and educators. He is a graduate of Johns Hopkins School of Medicine, Baltimore, where he is now associate professor of obstetrics and gynecology, and the author of two books and co-editor with Dr. Stone. The 1946 winners of the awards were Drs. Robert L. Dickinson, New York, and Irl C. Riggin, Richmond, Va., health commissioner of the Virginia Department of Health.

American Board of Surgery.—At a meeting of the American Board of Surgery in Philadelphia Dec. 13-14, 1946, the following resolution was adopted.

> The organization of the American Board of Surgery was completed on Jan. 9, 1937. A plan of this organization had been carefully studied by a general committee representative of certain general and sectional surgical societies called together through the initiative of the American Surgical Association. As a result of the deliberations of this general committee a tentative plan of organization was adopted This plan was reported to the cooperating surgical societies and was approved with the understanding that the board, when organized, would have the power to change or modify the proposed plan as it saw fit This board has been created in accordance with the action of the Advisory Board for Medical Specialties as approved by the Council on Medical Education and Hospitals of the American Medical Association, which has named certain specialty fields as being suitable to be represented by such boards. These boards have the twofold purpose of certifying those found to be qualified after meeting reasonable requirements and of improving existing opportunities for the training of specialists within the field concerned This is to be done for the protection of the public and the good of the specialty.

The cooperating surgical societies selected jointly to form the board appointed their representatives as follows: American Surgical Association, 3; surgical section of the American Medical Association, 3; American College of Surgeons, 3; Southern Surgical Association, 1; Western Surgical Association, 1; Pacific Coast Surgical Association, 1; New England Surgical Society, 1; total, 13

The term of membership is for six years Each cooperating association has the appointing power of its representatives subject to the approval of the board During the ten years in which the board has functioned, twenty-seven different surgeons have served full or partial terms of membership. The board has discharged its responsibilities by conducting examinations and has issued certificates of qualification to those surgeons who have met certain clearly specified educational requirements and have passed successfully its examinations In discharging its responsibilities, the primary purpose of the board has been to establish and maintain a high standard in the education and training of the young surgeon. The American Board of Surgery is not concerned with measures that might gain special privileges of recognition for its certificants in the practice of surgery. It is neither the intent nor has it been the purpose of the board to define requirements for membership on the staffs of hospitals. The prime object of the board is to pass judgment on the education and training of broadly competent and responsible surgeons —not who shall or shall not perform surgical operations. The board specifically disclaims interest in or recognition of differential emoluments that may be based on certification.

CORRECTION

Schweizerische medizinische Wochenschrift.—The index and abstracts from the *Schweizerische medizinische Wochenschrift* appearing on page 141 of The Journal of January 11 were taken from the August 31 rather than the August 24 issue of that publication.

Marriages

Bruno J. Romeo, Jackson Heights, N. Y., to Miss Evelyn Cordell of Asheville, N. C., and Washington, D. C., June 22.

Thaddeus A. Nigborowicz, Gallitzin, Pa, to Miss Blanche Elizabeth Romerowicz of Altoona July 14.

Hugh Lewis Williams, Martinsville, Ind., to Miss Marian Mead Reynolds of Scio, N. Y., July 27.

David B. Kagan, Pittsfield, Mass., to Miss Irene Sylvia Besdin of Syracuse, N. Y., in August.

Howard Lamar Holley, Marion, Ala., to Mrs. Martha H. Gross of Birmingham in September.

Carroll H. Smith Jr., La Mesa, Calif., to Dr. Margaret Stebbins of Pittsburgh July 27.

Robert M. Hoyne, Urbana, Ill, to Miss Avonne Andrews of Champaign July 26.

Milton M. Coplan, Miami, Fla., to Miss Mildred Elizabeth Hunt July 14.

Deaths

John Staige Davis ⊕ widely known plastic surgeon died at his home in Baltimore, Dec. 23, 1946, aged 74. Dr. Davis was born in Norfolk, Va., Jan. 15, 1872. After graduating at St. Paul's School, Garden City, L. I., he entered the Sheffield Scientific School at Yale University for premedical work under Professor Russell H. Chittenden, graduating in 1895. At Yale he was captain of the Sheffield Military Company and an editor of the *Yale Scientific Monthly*. He then went to Johns Hopkins University Medical School, Baltimore, graduating in 1899, and became a resident house officer in Johns Hopkins Hospital, serving under Drs. Osler, Halsted and Kelly. Later he was resident surgeon at Union Memorial Infirmary under Dr. J. M. T. Finney for three years.

At the completion of his hospital service Dr. Davis began private practice and was connected with the surgical dispensary of Johns Hopkins Hospital and with the Robert Garrett Children's Hospital. In 1908 he limited his practice to surgery, with particular attention to the then undeveloped field of plastic surgery. He is said to have been the first surgeon in the United States to specialize in general plastic surgery. Since 1923 he had been associate professor of surgery (plastic) at his alma mater, where in June 1946, after relinquishing some of his more arduous duties, he had been named associate professor of surgery emeritus. He had been instructor in anatomy and in operative surgery at the College of Physicians and Surgeons in Baltimore and professor of surgery at the Woman's Medical College of Baltimore. He was a founder member of the American Board of Plastic Surgery (chairman at the time of his death), the American College of Surgeons and the American Board of Surgery.

Dr. Davis served as vice president of the American Surgical Association and president of the American Association of Plastic Surgeons, the Southern Surgical Association and the American Association of Plastic Surgeons. He was a member of the Interurban Surgical Association, Surgical Research Society, American Association for the Surgery of Trauma, American Association of Reconstructive and Plastic Surgeons, the Southern Medical Association and others. During World War I he was a captain in the medical corps of the U. S. Army and was on duty in Baltimore as chairman of the examining board of the Medical, Sanitary and Veterinary Corps of Maryland. During World War II he was a member of the Plastic and Maxillofacial Surgery Committee of the Medical Section of the National Research Council, consultant to the Secretary of War and consultant in plastic surgery to the surgeon general.

Dr. Davis was visiting plastic surgeon at the Johns Hopkins Hospital, the Union Memorial Hospital, the Hospital for Women of Maryland and the Children's Hospital School. For about ten years he carried out research problems in the Hunterian Laboratory of Experimental Surgery and published articles dealing with these investigations. Dr. Davis was the author of "Plastic Surgery, Its Principles and Practice" and numerous articles in the field of plastic surgery. He was a member of the Maryland Club, Bachelors Cotillon, Yale Club of New York, Military Order of the World War, Sons of the American Revolution and the Maryland Historical Society.

William Hale ⊕ Utica, N. Y.; born in Gananoque, Ont., Canada, in 1886; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1910; president of the Medical Society of the State of New York; past president and secretary of the Oneida County Medical Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association, 1944-1945; a charter member of the Utica Academy of Medicine; commissioned in the British army and attached to a hospital reinforcement group during World War I, serving overseas, winning the British Military Cross; organized preschool clinics for the Child Welfare Department of Utica and helped bring about the merger of the Utica Visiting Nurse Association and the Child Welfare Association, serving the joint organization as medical director for four years; consulting surgeon at Utica State Hospital; served as president and as surgeon of the staff of the Faxton Hospital; for twenty years surgeon to the New York Central Railroad Company, Delaware, Lackawanna & Western Railroad Company and the New York, Ontario & Western Railroad Company; found dead in a parking lot at the rear of his office, January 16, aged 60, of heart disease.

Philip Arzt Kees ⊕ West Springfield, Mass.; University of Minnesota Medical School, Minneapolis, 1936; received master of science degree in surgery from the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania, Philadelphia; interned at the Los Angeles County Hospital in Los Angeles; served a residency at the William W. Backus Hospital in Norwich, Conn.; diplomate of the National Board of Medical Examiners; fellow of the Springfield Academy of Medicine; began active duty as a captain in the medical corps, Army of the United States, on March 1, 1942; service terminated with the rank of major in February 1946; chief of surgery at army air base hospitals, orthopedic surgeon of an evacuation hospital and operating surgeon of a paratroop combat team (11th Airborne) in the Pacific; wounded three times; decorated with the Purple Heart, Bronze Star for valor and the Silver Star for gallantry in action; on the staffs of the Mercy and Wesson hospitals; died Nov. 4, 1946, aged 38, of a skull fracture received in an automobile accident.

Carl Clifton Garver ⊕ Commander, M. C., U. S. Navy, Atlanta, Ga.; Emory University School of Medicine, Atlanta, 1932; formerly an intern and chief resident surgeon at the Grady Hospital; served as chief surgeon for the Georgia Power Company; commissioned a lieutenant in the medical corps of the U. S. Naval Reserve; began active duty in February 1941; promoted to lieutenant commander and commander; transferred to regular navy; after recruiting duty in Macon went to sea aboard the U. S. S. *Atlanta* and survived the sinking of the vessel in sea action off Guadalcanal; saw duty aboard five other ships before returning to the United States; received a letter of commendation from Admiral William Halsey for zealous performance of duty under severe combat conditions; drowned Sept. 10, 1946, aged 43, when he apparently fell from his private boat en route from Parris Island, S. C., to Jacksonville, Fla.

Charles Marshall Davison ⊕ Chicago; born on April 16, 1896; University of Illinois College of Medicine, Chicago, 1920; at one time assistant and associate in surgery at his alma mater; associate professor of surgery at the Northwestern University Medical School, where he had been assistant professor of surgery; professor of surgery at the Cook County Graduate School of Medicine; member of the Western Surgical Association and of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; attending surgeon and medical director of the University Hospital, where he served an internship; chairman of the department of surgery, formerly an intern and from Dec. 1, 1939 to May 16, 1943 medical director of the Cook County Hospital, where he had joined the surgical staff in 1926; died Dec. 16, 1946, aged 50, of coronary disease.

Carl Marion Sautter, New York; Indiana University School of Medicine, Indianapolis, 1911; specialist certified by the American Board of Otolaryngology; formerly clinical professor of rhinology and laryngology at the New York Polyclinic Medical School and Hospital; member of the American Laryngological, Rhinological and Otological Society; served during World War I; on the staffs of the Lawrence Hospital in Bronxville, New York Orthopedic Dispensary and Hospital, St. Luke's Hospital and the Misericordia Hospital; died Nov. 3, 1946, aged 59, of carcinoma of the prostate.

Edward C. Leverett Adams ⊕ Columbia, S. C.; Maryland Medical College, Baltimore, 1903; Medical College of South Carolina, Charleston, 1904; served during the Spanish-American War and in France during World War I; died Nov. 1, 1946, aged 70, of cirrhosis of the liver.

Mordecai Lee Barefoot, Dunn, N. C.; University of Maryland School of Medicine, Baltimore, 1911; died Nov. 27, 1946, aged 64, of diabetes mellitus and chronic nephritis.

Charles P. Bartley, Excelsior Springs, Mo. (licensed in Missouri in 1900); died Oct. 14, 1946, aged 79.

Louis De Keyser Belden ⊕ Indianapolis; Johns Hopkins University School of Medicine, Baltimore, 1915; interned at the Roosevelt and Bellevue hospitals in New York; a medical officer during World War I; on the staffs of St. Vincent's and City hospitals; died Nov. 28, 1946, aged 57, of coronary thrombosis.

Clarence Conrad Bosselmann, Plymouth, Ind.; Indiana University School of Medicine, Indianapolis, 1935; member of the American Medical Association; interned at the Lutheran Hospital; served as county coroner and in the U. S. Navy during World War II; on the staff of the Parkview Hospital; died Nov. 7, 1946, aged 36.

Norbert Odeon Bourque, Chicago; National Medical University, Chicago, 1904; University of Nashville (Tenn.) Medical Department, 1907; Université de Lausanne Faculté de Médecine, Switzerland, 1923; on the staff of the Mother Cabrini Hospital, where he died Nov. 23, 1946, aged 69, of auricular fibrillation and coronary sclerosis.

Albert Fessenden Bronson ⊕ De Land, Fla.; Bellevue Hospital Medical College, New York, 1885; member of the Medical Society of the State of Pennsylvania; died Dec. 10, 1946, aged 86, of arteriosclerosis.

William Edward Butt, Viroqua, Wis.; Chicago Homeopathic Medical College, 1895; died Nov. 20, 1946, aged 76, of myocarditis.

John Dennis Carr, Whitfield, Miss.; Jefferson Medical College of Philadelphia, 1896; member of the American Medical Association; served overseas during World War I and on the medical staffs of Kansas, Arizona and Mississippi State hospitals; formerly superintendent of North Dakota State Hospital in Jamestown; died Nov. 29, 1946, aged 74, of coronary thrombosis.

Edward Wight Clarke ⊕ Hastings-on-Hudson, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1919; past president of the Bergen (N. J.) County Medical Society; on the staff of the Englewood (N. J.) Hospital; died in the Columbia-Presbyterian Medical Center in New York, Nov. 19, 1946, aged 54.

Henry Little Clarke, Brewster, Mass.; Boston University School of Medicine, 1884; died in Boston Nov. 17, 1946, aged 87, of arteriosclerosis and fracture of the left femur.

Vincent Jacob Cohenour ⊕ Joliet, Ill.; Northwestern University Medical School, Chicago, 1901; served during the Spanish-American War and as county physician; died Nov. 27, 1946, aged 73, of uremia.

James A. Cravens, Greenfield, Ill.; Washington University School of Medicine, St. Louis, 1896; for many years on the staff of the Jacksonville (Ill.) State Hospital; died at Our Saviour's Hospital, Jacksonville, Nov. 30, 1946, aged 74, of coronary thrombosis.

John B. Davis, Ottawa, Kan.; Medical College of Ohio, Cincinnati, 1894; died Oct. 2, 1946, aged 77, of coronary thrombosis.

Frank Herbert Deane, Berwyn, Ill.; Dearborn Medical College, Chicago, 1906; for many years on the board of health; served overseas during World War I; examiner for the Selective Service Board and awarded a presidential citation for special services rendered during World War II; died Nov. 20, 1946, aged 77, of coronary disease.

William G. Doern, Daytona Beach, Fla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; member of the American Medical Association; professor of anatomy at the Milwaukee Medical College; Spanish-American War veteran; medical examiner of recruits in Milwaukee during World War I; died in Milwaukee Nov. 3, 1946, aged 68, of heart disease.

Joseph Donohoo, Tulsa, Okla.; University of Nashville (Tenn.) Medical Department, 1892; died in a local hospital Nov. 1, 1946, aged 77, of hypertensive heart disease.

David G. Elder, Chickamauga, Ga.; Atlanta Medical College, 1886; member of the American Medical Association; died recently, aged 82.

George William Farrar, Fall River, Kan.; University Medical College of Kansas City, Mo., 1895; died in St. Francis Hospital, Wichita, Oct. 20, 1946, aged 76.

Frank W. Foster, Hannibal, Mo.; Louisville (Ky.) Medical College, 1894; died Oct. 13, 1946, aged 74.

Broox Cleveland Garrett ⊕ Shreveport, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1913; served during World War I; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; past president of the Shreveport Medical Society; member of the board of Caddo-Shreveport Health Unit; member staff, which he served as president, of Schumpert Sanitarium; on the visiting staff of Charity Hospital; died Nov. 15, 1946, aged 58.

Albert Alexander Gebhardt, St. Louis; St. Louis College of Physicians and Surgeons, 1909; served during World War I; found dead Nov. 12, 1946, aged 73.

Mark Albert Glaser ⊕ Los Angeles; University of California Medical School, San Francisco, 1923; interned at San Francisco County Hospital; member of the Los Angeles Neurological Society, Hollywood Academy of Medicine, Western Association of Industrial Physicians and Surgeons and the American Association of Industrial Physicians and Surgeons; on the staffs of Kern General Hospital, Bakersfield, Hollywood, Methodist and Cedar of Lebanon hospitals; died in Salt Lake City Nov. 2, 1946, aged 49.

George W. Goss, Los Angeles; Saginaw (Mich.) Valley Medical College, 1899; died Nov. 4, 1946, aged 76.

John L. Hadley, Oil City, Pa.; Cleveland Medical College, Homeopathic, 1897; member of the American Medical Association; past president of the Venango County Medical Society; member of the board of directors of the Standard Life Insurance Company of America; formerly member of the city board of health; served as vice president and member of the staff of the Oil City General Hospital, where he died Nov. 13, 1946, aged 81, of cardiorenal vascular disease.

John Kennedy Hanna, Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1884; died in the Butterworth Hospital Nov. 19, 1946, aged 88, of carcinoma of the prostate and injuries received in a fall.

Charles D. Harrington ⊕ Wayzata, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1895; died Nov. 18, 1946, aged 76, of carcinoma of the lung.

Caleb Wooster Harris, Bishopville, S. C.; University of Nashville (Tenn.) Medical Department, 1894; Vanderbilt University School of Medicine, Nashville, 1894; served in the state legislature from Lee County from 1907 to 1911; died Oct. 20, 1946, aged 75.

Martin Hassenmiller, West Baden Springs, Ind.; Louisville (Ky.) Medical College, 1901; member of the American Medical Association; past president of the West Baden National Bank; died in Louisville, Ky., Nov. 18, 1946, aged 77, of cerebral hemorrhage.

Ira H. Hawes, Arcanum, Ohio; Medical College of Ohio, Cincinnati, 1893; member of the American Medical Association; on the staff of Wayne Hospital in Greenville; died Nov. 27, 1946, aged 79, of cerebral hemorrhage.

Edgar Marion Hazlett, Washington, Pa.; Jefferson Medical College of Philadelphia, 1902; member of the American Medical Association; for many years president and on the board of the Washington County Tuberculosis Association; member of the local Civil Service Board and board of health; on the staff of the Washington Hospital, where he died Nov. 8, 1946, aged 76, of cerebral hemorrhage.

Charles Martin Hutchinson, Cambridge, Mass.; Dartmouth Medical School, Hanover, N. H., 1894; member of the American Medical Association; school physician; on the staff of the Cambridge Hospital, where he died Nov. 26, 1946, aged 76, of paralytic ileus following an operation for carcinoma of the sigmoid.

Stella Elora Chapman Jacobi, Omaha; University of Michigan Homeopathic Medical School, Ann Arbor, 1885; died Nov. 12, 1946, aged 87, of cerebral hemorrhage.

Norman Gilchrist James, Hayneville, Ala.; Medical College of Alabama, Mobile, 1898; member of the American Medical Association; died Nov. 19, 1946, aged 72, of Hodgkin's disease.

Simeon Lambright, Danville, Ill.; National Normal University College of Medicine, Lebanon, Ohio, 1892; member of the American Medical Association; died in Mishawaka, Ind., Nov. 9, 1946, aged 83, of cardiovascular disease.

Mial R. Lyman, Bad Axe, Mich.; Eclectic Medical Institute, Cincinnati, 1883; died Nov. 2, 1946, aged 90.

James Riley McCollum, St. Marys, W. Va.; College of Physicians and Surgeons, Baltimore, 1900; member of the American Medical Association; honorary member of the Academy of Medicine of Parkersburg and the West Virginia State Medical Association; formerly member of the West Virginia House of Delegates; in September 1946 was unanimously named as the "Good, Good Neighbor of Pleasants County"; died Nov. 15, 1946, aged 72, of coronary occlusion.

Edward Aloysius McCullough, Meriden, Conn.; Harvard Medical School, Boston, 1894; served during the Spanish-American War; died in the Meriden Hospital Nov. 24, 1946, aged 78, of heart disease.

Royal Albert McCune ⊕ Surgeon Lieutenant Commander, U. S. Navy, retired, Central Valley, N. Y.; University and Bellevue Hospital Medical College, New York, 1904; U. S. Naval Medical School, 1928; entered the U. S. Navy in December 1920 and retired on Feb. 1, 1941 on attaining the statutory retirement age; died in Watertown, Mass., Nov. 23, 1946, aged 69, of carcinoma of the larynx.

Joseph John Manley, Cleveland; St. Louis University School of Medicine, 1929; interned at St. Alexis Hospital in Cleveland, where he was resident physician at the Charity Hospital; began active duty as a captain in the medical corps, Army of the United States, in October 1942 and service terminated in August 1943; died in the U. S. Marine Hospital recently, aged 46, of arteriosclerotic heart disease.

Henry B. Mehrmann, Oakland, Calif.; California Medical College, Oakland, 1885; member of the American Medical Association and the Alameda County Sanity Commission; served as county coroner and as Alameda County Public Administrator; died in the Merritt Hospital Nov. 4, 1946, aged 82, of arteriosclerotic heart disease.

Lewis Franklin Mobley ⊕ Summitville, Ind.; Medical College of Indiana, Indianapolis, 1902; served overseas during World War I; on the staff of St. John's Hospital in Anderson; died in the Ball Memorial Hospital, Muncie, Nov. 8, 1946, aged 71, of cerebral hemorrhage.

George Wilson Montgomery, Louin, Miss.; University of Mississippi School of Medicine, University, 1910; served during World War I; died Nov. 27, 1946, aged 69, of cerebral hemorrhage.

West Montgomery, Mentor, Ohio; Starling Medical College, Columbus, 1885; past president, vice president and secretary-treasurer of the Lake County Medical Society; justice of the peace; served as mayor of Ada; on the staff of the Lake County Memorial Hospital in Painesville; died recently, aged 88, of cerebral thrombosis.

Henry Paul Murphy, Philadelphia; Medico-Chirurgical College of Philadelphia, 1905; died Nov. 9, 1946, aged 67, of heart disease.

Harry Manlove Nutter, Philadelphia; Baltimore University School of Medicine, 1903; for many years on the staff of the Jefferson Hospital; died in Oaklyn, N. J., Nov. 12, 1946, aged 71, of coronary thrombosis.

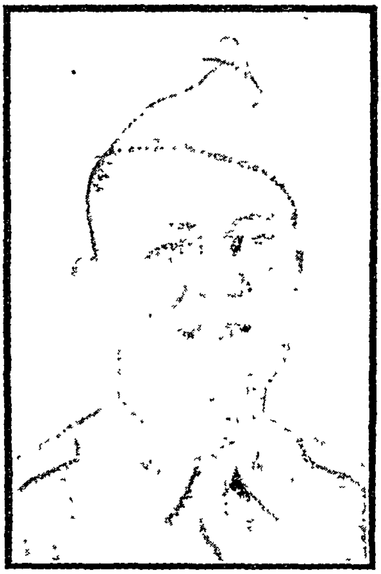
Benjamin Stuart Paschall, Seattle; University of Pennsylvania Department of Medicine, Philadelphia, 1903; died Nov. 22, 1946, aged 67.

James M. Pedicord, Zanesville, Ohio; Ohio Medical University, Columbus, 1893; served as county coroner; formerly on the staffs of the Good Samaritan and Bethesda hospitals; died recently, aged 78, of cardiac decompensation.

Benjamin Anthony Pizzuto, Jersey City, N. J.; Georgetown University School of Medicine, Washington, D. C., 1938; interned at St. Francis Hospital in Jersey City and New York; served during World War II; died recently, aged 33.

Ernest Otto Pucklitsch, Cincinnati; Miami Medical College, Cincinnati, 1894; died Nov. 2, 1946, aged 77, of coronary occlusion.

Jack Roy Tayman Rafter ⊕ Berkeley Springs, W. Va.; Medical College of Virginia, Richmond, 1940; member of the Kentucky State Medical Association; interned at the Good Samaritan Hospital in Lexington, Ky., where he had been resident physician at the University of Kentucky from 1941 to 1943, when he became affiliated with the Fuller-Gilliam Hospital in Mayfield, serving until 1945; died in an automobile accident Oct. 22, 1946, aged 32.



Capt. Wilbert W. Buckhold M. C., A. U. S., 1907-1944

Leonard Sigmund Rau, New York; Bellevue Hospital Medical College, New York, 1885; fellow of the American College of Surgeons; served as police surgeon and health officer in Lawrence, N. Y.; for many years president of St. Joseph's Hospital in Far Rockaway, where he had been on the staff; served on the staffs of the Meadowbrook Hospital in Hempstead, N. Y., and the Nassau Hospital in Mineola, N. Y.; died Oct. 31, 1946, aged 82.

Joseph C. Reeder, Montezuma, Ind.; Eclectic Medical Institute, Cincinnati, 1886; died Nov. 28, 1946, aged 91, of uremia.

Frederick Knox Reynolds, Birmingham, Ala.; Birmingham Medical College, 1901; died Nov. 4, 1946, aged 75.

John I. Rinne Jr., Indianapolis; Indiana University School of Medicine, Indianapolis, 1936; member of the American Medical Association; interned at the Indianapolis City Hospital; interned at the New York Hospital in New York, where he served a residency; during World War II attained the rank of lieutenant commander, after three and one-half years in the U. S. Navy, including eighteen months overseas; killed in an automobile accident Nov. 9, 1946, aged 34.

David N. Robb, Ypsilanti, Mich.; Detroit College of Medicine and Surgery, 1930; member of the American Medical Association; interned at the City of Detroit Receiving Hospital; served as health officer of Ypsilanti and as county coroner; died Nov. 12, 1946, aged 48.

Joseph Rosenfeld, Youngstown, Ohio; Long Island College Hospital, Brooklyn, 1915; fellow of the American College of Physicians; during World War I served as a captain in Russia with an American ambulance corps and was decorated for bravery, receiving the French Croix de Guerre as well as the St. Ann's Cross from the provisional government of Archangel, Russia; died Nov. 4, 1946, aged 53, of tumor of the lung and pleura.

William John Garvey Salmon, Old Forge, Pa.; College of Physicians and Surgeons, Baltimore, 1908; member of the American Medical Association; deputy coroner of Lackawanna County; medical examiner in the schools of Old Forge; served as Selective Service examiner for Old Forge and Clarks Summit during World War II; one of the organizers of the Miners' and Merchants' Bank; died Nov. 18, 1946, aged 65.

Paul Francis Sarubbi, New York; Eclectic Medical College, Cincinnati, 1915; served as police surgeon; died in St. Vincent's Hospital Nov. 28, 1946, aged 56, of liposarcoma.

Otto Ransom Spigler ⊕ Terre Haute, Ind.; Hospital College of Medicine, Louisville, 1902; served during World War I; fellow of the American College of Surgeons; on the staffs of St. Anthony's and Union hospitals; surgeon, St. Mary of the Woods School and Chicago, Milwaukee, St. Paul and Pacific Railway; vice president of the Terre Haute Savings Bank; died Nov. 28, 1946, aged 71, of coronory occlusion.

James Oscar Starr, Greenville, Ohio; Starling Medical College, Columbus, 1901; formerly vice president and secretary of the Darke County Medical Society; died in Dayton recently, aged 77, of arteriosclerosis.

John Joseph Thomas, Ansonia, Conn.; Fordham University School of Medicine, New York, 1921, member of the American Medical Association; interned at St. Catherine's Hospital in Brooklyn; on the staff of the Griffin Hospital in Derby, where he died Oct. 14, 1946, aged 49.

William Alonzo Tolson, Washington, D. C.; Howard University College of Medicine, Washington, 1906; died Nov. 29, 1946, aged 62, of carcinoma of the stomach.

Roscoe Samuel Van Pelt ⊕ Los Angeles; Northwestern University Medical School, Chicago, 1909; died in Guadalajara, Mexico, Nov. 13, 1946, aged 65, of heart disease.

Charles Edwin Verdier, New Orleans; Hahnemann Medical College and Hospital of Philadelphia, 1904; medical director of the Public Health Institute, which he was instrumental in founding; major in the medical corps of the U. S. Army during World War I and later a major of the Louisiana National Guard; died Nov. 17, 1946, aged 63.

Joseph P. Walsh ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1895; served as a major in the medical corps of the U. S. Army during World War I; past president of the Pennsylvania Society for the Prevention of Tuberculosis; member of the American College of Chest Physicians; associated with the Henry Phipps Institute for Study, Treatment and Prevention of Tuberculosis, St. Agnes Hospital and White Haven (Pa.) Sanatorium; died Oct. 23, 1946, aged 75, of coronary sclerosis.

KILLED IN ACTION

Wilbert William Buckhold, Blackey, Ky.; University of Louisville School of Medicine, 1933; served as health director of Meade County; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army in August 1940; promoted to captain; stationed at Fort Knox, Ky., till late in 1941, when he was transferred to the U. S. Army Sternberg General Hospital in Manila; believed to have been captured on Corregidor; killed in action in the South China Sea Oct. 24, 1944, aged 37, as the result of the sinking of a Japanese ship on which he was being transported while a prisoner of war.

Investigation of the Causation of Rheumatoid Arthritis

An attempt on a large scale to discover the cause of rheumatoid arthritis was announced by Lord Horder in presiding at the annual meeting of the Empire Rheumatism Council On the recommendation of the scientific advisory committee the council has appointed two whole time registrars to investigate the factors in the causation of rheumatoid arthritis It has been decided to begin with 100 token cases If this preliminary piece of clinical research is promising, it is intended to investigate 1,000 cases A carefully prepared questionnaire and case note has been produced by the committee, which will facilitate the revelation and correlation of new facts in connection with rheumatoid disease This investigation has been in progress for about three months From it the committee hopes that there will emerge the lines on which specific research should be undertaken This is the first time that an attempt has been made by a uniform method of approach to discover the cause of rheumatoid arthritis—a disease of which, while being the most crippling, we know least So far from 70 to 80 of the first 100 cases have been investigated in hospitals in or near London An indication of the thorough nature of the investigation into each case is the fact it takes about four hours to fill in one questionnaire When the first hundred token cases have been completed it is hoped, if sufficient funds are available, to appoint four more registrars to complete the investigation It is estimated that it will take six months to complete the first hundred cases with an equal number of controls The other cases, with their controls, will be drawn from other parts of the country, so that it can be seen whether the incidence of the disease is higher in one place than in another and whether local conditions affect it

The Interference of Bureaucracy in Medical Work

If there is one thing more than another which the profession dreads in the working of the National Health Service it is bureaucratic interference Some bad examples of this interference, though not in connection with the act, have recently come to light and are regarded as a foretaste of what to expect under the act They have excited widespread condemnation in the profession and regret that they did not occur in time to be known to all voters in the plebiscite whether to negotiate or not with the government It is maintained that many who voted "Yes" would have voted "No" if they had had such examples of interference before them One bad example, the attempt of the Willesden Borough Council to force the doctors and nurses employed by it to join a trade union under penalty of dismissal, has been reported in a previous letter An equally bad example is reported by a doctor in the current issue of the *British Medical Journal* He had under care a patient suffering from carcinoma of the esophagus who was discharged from the hospital after gastrostomy had been performed, the growth having been found irremovable The patient had lost over 12 6 Kg in weight, and the hospital dietetic expert, in agreement with the consulting surgeon, decided that he should have 2 ounces (60 Gm) of fat daily in the form of butter or margarine As the dietetic restrictions of the war still continue, this could be obtained only by the sanction of the food authorities A special form had to be filled in by the doctor giving full particulars of the patient's condition and the medical reasons for the extra ration The local food officer granted the extra fat, but he had to report the matter to headquarters and a few days later received a reply stating that "our medical officers are of opinion that in cases of gastrostomy the important point is that the food chosen is such as will go through the gastrostomy tubes In their opinion there is no need for extra butter in such cases, as there is no call for a lubricant" They offered instead a priority allowance of 2 pints (1,000 cc) of milk and three eggs per week The doctor then wrote to Dr Edith Summerskill, parliamentary secretary to the Ministry of Food, because he felt that it was wrong to reduce his patient's fat ration, as he was only just holding his own in weight He pointed out that the patient was not ordered butter as a lubricant for swallowing but as supplying extra fat as considered necessary by the dietetic expert Also the ministry had missed the point that the extra fat was necessary to maintain life Dr Summerskill replied stating that the refusal was "strictly in accordance with the recommendation of our medical advisers," but "on compassionate grounds" an extra 2 ounces of butter weekly would be allowed The doctor indignantly comments on describing thus what was necessary to maintain life The patient did not live much longer Such are the mistakes made by officialdom when it interferes with the work of the physician

The Failure of Breast Feeding

One of the tragedies of our civilization is the failure of breast feeding In the *Archives of Disease in Childhood* (**21**:1 [March] 1946) Harold Waller tries to determine why failure occurs in about half the mothers The statistics of the Ministry of Health show that 80 per cent of the babies leaving maternity hospitals and 95 per cent of those born outside are wholly breast fed at the end of the first fortnight of life, yet three months later only 50 per cent are still breast fed Primiparas contribute largely to the failures Of 436 primiparas seen consecutively at infant welfare centers in East London 28 per cent at the end of one month, 38 per cent at the end of two months and 42 per cent at the end of three months had ceased to feed their children, giving as a reason only that "the milk left them" Waller gives two major reasons The first is that the nipple is structurally defective, but he believes that this defect can be easily remedied by wearing a glass shield with a controlled opening, which is firmly supported over the breast so as to press the nipple through the opening The second reason is that the breasts develop a high milk pressure and become hot and heavy and enlarged to perhaps twice their size The skin is tightly stretched and glistening, and the veins are prominent At the height of the engorgement milk cannot be obtained by the child, and only with difficulty is it removed artificially The mother feels great discomfort and suckling damages the nipples and may lead to abscess of the breast

The treatment in the extreme stage of engorgement is manual relief of the breast by the mother or nurse, who with thumb and finger compresses the lacteal sinuses The excess of milk is given to the child Waller's practice is to prevent this stage from developing by teaching all mothers to massage the breasts during the last stages of pregnancy so that if there is any trouble she can treat herself

Cancer Research

At the annual meeting of the British Empire Cancer Campaign it was stated that a record income of $520,000 had been raised during the year Investigation by the scientific advisory committee into the influence of viruses in the causation of cancer and a vast amount of work in the field of chemotherapy were proceeding New methods of attack were also being developed by application of the most recent nuclear physics to treatment A surgeon Sir Stanford Cade, in moving the adoption of the report, said that the best yardstick by which to measure progress was mortality. Of cancer in accessible sites and in some internal organs it could be said that there was considerable decrease in mortality. Although in some sites, notably in the lung, the curve was still relentlessly on the upgrade, the rate for the lip, tongue, jaw, skin, breast and uterus was falling. It was undesirable to talk about cure, but Professor Dodds had given us a new weapon. The synthetic ovarian hormone diethylstilbestrol and its derivatives were potent in the clinical control of cancer of the prostate and possibly of other sites.

PARIS

(From Our Regular Correspondent)

Dec. 31, 1946.

The Paris Conference of the United Nations Educational, Scientific and Cultural Organization

In 1921 on the proposal of Léon Bourgeois (France) the Society of Nations appointed a commission, of which Henri Bergson was president, to examine international intellectual cooperation. In Paris the International Institute of Intellectual Cooperation, with which forty national commissions and numerous committees of experts collaborated, was created. In 1942 in London the Allied ministers for education met periodically to discuss the cultural reconstruction of occupied and devastated Europe. Then in 1945 in San Francisco the creation of a special organization was completed. On Nov. 1, 1945 UNESCO was organized in London and to its program were added sciences and information of the masses; forty-four nations signed the UNESCO convention.

The Paris Conference took place from Nov. 19 to Dec. 10, 1946. The French government put at the disposal of UNESCO the Majestic Hotel, former head office of the Paris gestapo. Forty-eight national delegations were present. The chief of the United States delegation was William Benton, under state secretary to the foreign office, with four delegates, five deputy delegates and thirty-three counselors. Other countries were represented by similar delegations. Seven nations of the United Nations Organization which have not signed the UNESCO charter, Russia, the Ukraine, Bielo-Russia, Costa Rica, Ethiopia, Honduras and Paraguay, did not send delegations.

PROGRAM, AIM AND WORKING METHOD

The secretary to the executive committee of UNESCO, Dr. Huxley, author of the book "UNESCO, Its Purpose and Its Philosophy," has indicated in his report to the conference the two main aims of UNESCO: first to contribute to peace and then to work for the happiness of humanity regardless of races, sexes, languages and religions, against every racism theory, by conforming oneself to the principle of equality, to guarantee to everybody full and equal access to education and the mutual respect between men and nations. An important task is reconstruction in the sphere of culture and science. One problem of prime importance in the direction of liquidating inequality is the fight against illiteracy. During 1947 a conference will establish throughout the world the ten UNESCO centers. They will partake of the same roof as the regional United Nations organizations for health, civil aviation, food and agriculture.

SUBCOMMISSION FOR NATURAL SCIENCES

The program of this subcommission has been prepared under the leadership of Joseph Needham, assistant professor of biochemistry at the Cambridge University and foreign professor of physiology at Stanford University. This subsection has been in communication with eighty-four international scientific organizations.

NATURAL SCIENCES PROGRAM

This program covers a wide range of projects, some of which are to be put into operation forthwith and others only to be studied and reported on to the next general conference.

FIELD TEAMS FOR THE STUDY OF NUTRITION

The highest priority was given to the important plan of establishing field teams for the study of nutrition problems, one in India (where already a small institute for researches on food is located at Coonor; it will also deal with the role of fish as food, which nourishes 60,000,000 of Bengalese), one in Hylean Amazon, one in China and later, when conditions permit, one in Africa. The aim of the field teams is to investigate all aspects of food production and utilization, deficiency diseases and other problems with the ultimate object of raising the standard of living for large masses of people in those great regions of the world now suffering from malnutrition.

OTHER NATURAL SCIENCE ACTIVITIES

Four field science cooperation offices will be set up in China, India, the Middle East and Latin America, staffed with scientific men engaged on every type of liaison work with the scientists of the region.

Assistance will be given in the scientific rehabilitation of the war devastated countries. The restoration of scientific libraries throughout the world will be facilitated through photographic reproductions and microfilms.

Grants-in-aid will be given for scientific work of international importance, such as type culture and collections of bacteria, algae, fungi and genetic mutants.

Grants will be allotted selected scientific expeditions and to aid existing international laboratories, such as the Marine Biological Station at Naples and the research laboratory on the Jungfraujoch.

Essential research equipment and material exchanges will be disseminated, notably by operating a scientific apparatus information bureau and by taking measures to overcome difficulties arising out of currency restrictions. A group of experts has already prepared a list of scientific instruments which includes already 20,000 items. The cost of equipment of various standard laboratories in various fields has been calculated.

The possibilities will be explored of creating new international laboratories for astronomy, applied mathematics (computing machines, for instance, to organize an exact method for a demographic survey), tropical diseases, oceanography and the migration of birds. The compilation of a world register of scientific institutions and scientists will be begun.

A plan is being urged to assist scientists in crossing national frontiers with their documents and scientific instruments.

Moreover, it has been decided, in agreement with the International Council of Scientific Unions, to resume the publication of scientific periodicals interrupted on account of the war. On the proposal of the Economic and Social Council of the United Nations Organization, UNESCO is to prepare a report on the organization of an international observatory, of a meteorological station in the Southern Hemisphere and of an international laboratory for studies on tuberculosis and another for food.

RELATIONS WITH OTHER SCIENTIFIC ORGANIZATIONS

The collaboration with other scientific organizations is of prime importance in order to avoid work on parallel lines and also in consideration of the restricted budget of UNESCO. A convention between UNESCO and the International Council of Scientific Union has been prepared. It consists in reciprocal consultation and representation, exchange of information and work in common for definite purposes. As regards relations with the World Health Organization, UNESCO contemplates taking over the purely scientific part of this organization and negotiations are in progress. A budget of $6,000,000 has been fixed covering the activity of all sections.

STRUCTURE OF ORGANIZATION

Every nation which is a member deputes a delegation of five representatives to the conference, which takes place every year; the next one will be in Mexico City in 1947.

SPAIN

(From Our Regular Correspondent)

MADRID, Dec. 10, 1946.

Medical Schools and Other Scientific Departments and Hospitals

At present the medical schools are functioning normally, though they do not seem to hold the high scientific rank they attained in the years before the civil war. Results too are rather below the former standard, owing chiefly to the lack of sufficiently trained and experienced educators. The filling of posts made vacant by the death, exile or political disqualification of their previous holders is still provided for by the outworn system of competitive examinations, now complicated by the fact that the ideological tendencies of candidates are taken into account and by the inadequate constitution of the boards of examiners, whose members are often not sufficiently trained in the specialties in question to be qualified to judge. Too often also recourse has to be had to the younger generation of teachers just out of school themselves and not fitted for the task of making a judicious selection, having furthermore only just occupied their own chairs. Notwithstanding all this, the voids are being gradually filled. Yet it is sad to see that men like J. F. Tello, T. Hernando, M. Varela Radio, J. Casas, B. Landete, E. Trobo (to name only a few from the Madrid Faculty of Medicine) and others who in the last twenty years had contributed by their high reputation abroad to the prestige of the Spanish medical schools are still excluded from the universities, although they are not absolutely deprived of their other civic rights. In recent months the hopeful rumor has got about that some who are living in Spain are to be reinstated, and Professor Marañon's return to his old functions seems to constitute a happy omen.

The aforementioned drawbacks are not so apparent in the hospitals in Madrid which are not attached to the university. True some old professors have been deprived of their posts—like Professor Manuel Tapia, and Professor I. Sanchez Covisa, who died recently—and they have not been replaced by really satisfactory men. However, some other excellent and already famous masters have entered the service, among them Professor C. Jimenez Diaz, Professor E. Oliver Pascual, Dr. J. Lopez Ibor (who has taken the place of the distinguished exile Professor G. R. Lafora), Dr. Benzo and Dr. R. Garcia Tapia, and from nearly all of these we are warranted in expecting fruitful work even if anything changes the political situation. Nevertheless, it is painful to think how scarce is the scientific production of the National Hospital for Infectious Diseases (the former Hospital del Rey) which, before the civil war, under the direction of Professor M. Tapia, did such great honor to Spanish medicine by its publications.

The most notable event in the field of medicine in the year 1945 was the return to his chair of endocrinology in the Madrid Faculty of Medicine of Professor Gregorio Marañon, who went into exile in 1936 but returned to Spain in 1943, not, however, without having overcome some difficulties. During his stay abroad he was one of the most eminent exponent of Spanish medical culture in various countries of America and Europe, where he has left, as a trace of his passage, a series of important books. The returning to him of his department in the Madrid General Hospital was gratifying; but his reinstatement in his chair in the university has caused joy to all in that corporation who so greatly deplored the lack of good teachers as well as in all intellectual spheres in the country. His masterly lectures in the past academic year gave a real impulse to the university: the clinical and scientific sessions began to grow in interest as a sign of work resumed in relatively poor circumstances and needing a powerful stimulus. The attendance was extremely large and, among others present, were many old masters and some of the present professors: a good proof of fraternal feeling. A course of weekly lectures was given by the best Spanish and well known foreign professors, including the Portuguese Professors Reynaldo Dos Santos and J. Cerqueira Gomes; while among the Spaniards were Professors T. Hernando, G. Marañon, J. Morros Sarda, E. Oliver Pascual, M. Tapia, J. Sacristan, J. Germain, P. Barceló, A. Duque Sampayo, Rodriguez y Perez and F. Vega Diaz. But among all these lectures, two given by Professor M. Tapia, now director of an important tuberculosis institution in Portugal, stood out, being imbued with their author's great clinical and pathologic experience; particular interest attaches to one on bronchial tuberculosis.

One more fact which contributes to the value of the resumption of work in Professor Marañon's clinic is the appearance of the *Boletin del Instituto de Patologia Medica,* similar in its purpose and contents to the *Proceedings of the Staff Meetings of the Mayo Clinic,* in which the basic work of this center is reproduced as well as certain novelties in clinical endocrinology.

BUENOS AIRES

(From Our Regular Correspondent)

Nov. 5, 1946.

Congress on Surgery

The Seventeenth Argentinean Congress of Surgery was recently held in Buenos Aires under the presidency of Dr. Pablo Mirizzi. The following physicians were official speakers: Enrique Castaño and A. Trabucco, "Trauma of Kidney"; Carlos E. Ottolenghi, "Open Fractures"; J. M. Delrio, "Treatment of Burns"; Lelio Zeno, "Sequels of Burns"; H. Marino, J. Piñero Sorondo and Carlos Ottolenghi, "Organization of Surgical Centers in Hospitals"; Alejandro J. Pavlovsky, "Diagnosis of Acute Occlusion of Small Intestine"; Oscar Copello, "Pseudotumors of Bones"; Dr. Allende, "Conceptions on Preoperative and Postoperative Periods." Surgical sessions and the exhibition of surgical films were parts of the program. The attendance at the congress was large.

Congress on Obstetrics

The Sixth Congress of Obstetrics and Gynecology met in Buenos Aires under the presidency of Arturo J. Risolía. The following physicians were official speakers: Josué A. Berutti on the forceps, and Jorge de Rezende of Rio de Janeiro and Enrique Thwaites Lastra of Buenos Aires on neoplasms in relation to pregnancy. Dr. Fred L. Adair of Chicago, who was especially invited, showed a film on "Delivery" and later lectured on "Rupture of Uterus."

Speakers for the second official topic were the following: Drs. Pablo Borrás of Rosario and Guillermo di Paola of Buenos Aires discussed the morphologic, glandular and psychic changes of adolescence. Drs. Luis D. Bottaro of Montevideo and Enrique Bazterrica of Buenos Aires discussed "Repercussion of Gynecologic Disorders on Urinary Apparatus of Women."

Meeting of Gastroenterologists

A meeting of Latin-American gastroenterologists and nutritionists was held under the auspices of the Sociedad de Gastroenterología y Nutrición of Buenos Aires, of which Dr. Pedro A. Maissa is the head. The main official topic was "Sigmoid Diseases Excluding Cancer." Drs. Julio Carrere of Uruguay, Mariano Castex, Carlos Bonorino Udaondo and Ivan Goñi Moreno of Buenos Aires were official speakers. By unanimous votes of Argentinean, Brazilian, Mexican and Uruguayan delegates, it was resolved to establish an Inter-American Association of Gastroenterology. A committee was appointed with Drs. Julio Carrere, Benigno Varela Fuentes and Carlos Alberto Estapé of Uruguay and Carlos Bonorino Udaondo, Oscar Copello and Pedro A. Maissa of Buenos Aires. The association will have headquarters in Buenos Aires. Inter-American congresses and medical works on gastroenterology will be arranged in the future by the association.

Correspondence

PSYCHIATRIC CASUALTIES

To the Editor:—In a communication in the Nov. 9, 1946 issue of The Journal Dr. Koontz raised an issue of great importance to both medicine and society today in his discussion of the high incidence of psychiatric cases during the recent war. Such an incidence is not, of course, confined to members of the armed forces: it is rather exaggerated in this case owing to the additional stress of circumstances and brought into prominence by the careful attention it receives. But I would not hesitate to suggest that peacetime periods of stress, such as those of depression, result in an equally high incidence of psychiatric "casualties," which in this instance do not have the benefit of medical assistance or even of diagnosis.

That the increasing amount of maladjustment is more than a simple medical problem is implied in Dr. Koontz's second suggestion of its cause, "a change in our political philosophy," but I do not believe that this formulation is accurate enough to lead us to a successful solution. The phrase "political philosophy" is not defined by the correspondent, although he characterizes it as affecting the "patriotism and sense of duty of a great mass of our citizens." I would prefer to say that the change has been much broader, involving the attitudes of and to the whole society in which we live, and that the change in patriotism and sense of duty is only one aspect of the changing psychology of the period.

It has been well shown by sociologists, anthropologists and those psychiatrists who have used the social approach that any culture passes through an evolution of growth, maturity and decay. During the early expansionist period, creative activity of all kinds is high: material, artistic and spiritual developments are great and new areas of human skill and thought are explored. Later the dominant forms emerging out of the earlier activity become apparent as characteristic of the society. Finally, development slows, expression becomes stereotyped and tends toward the bizarre, and quantity and quality of all activity degenerates. During the first two periods the individual finds a place in society: he feels he owes it something and is willing to sacrifice himself for the good of society because it offers him something outside himself. Creative opportunity enables, in fact encourages, him to turn outward and lose himself. At such times the amount of maladjustment is low. During the later period of contraction the individual's opportunities become more limited and his frustration increases. He feels no larger purpose outside himself and that he has little reason to cooperate with others and consequently fails to achieve or maintain mental health. In short, the morale of society is low: there is not only little patriotism and little sense of duty but increased delinquency, divorce and general signs of maladjustment. Efforts to alleviate the situation in material terms, as by government relief during a depression, do have a bad effect on a citizenry that has been taught to believe, and in fact demonstrated to itself, that it can be self sufficient. But this is only a secondary effect on an already low morale. That it can be rapidly overcome given the right conditions is demonstrated by the remarkably high morale during the war of the British people, who suffered as much as any one by the dole.

In the periods of contraction, with their consequent ill effects on the mental health of the people, attempts are made to relieve this symptom of disorder in the social organism. Many theories and courses of action are suggested. Religious revivalists point to sin as the cause and salvation as the cure. Fascists and Nazis ascribe the symptoms to too much democracy and hail dictatorship and race superiority as solutions. (It is easy to see how the frustrations of people at this time can be played on by antiracial propaganda.) The psychiatrist is one who approaches the problem scientifically, but as long as he deals only with individuals he will see only symptoms and seek in vain, as does Dr. Koontz, for the underlying etiology. Some psychiatrists have suggested that the cause lies in faulty child upbringing and that the solution is proper psychologic education. But, though this takes us back one step in the chain, we are still dealing only with symptoms; and who is to educate the educators? It is my belief that the new "tactical alinement" of which Dr. Koontz speaks is for psychiatry to adopt a study of society itself and of the relation of the individual to society, taking all it can of the knowledge and methods of those sciences which have already entered the field. It must seek answers to the fundamental questions Why is society no longer expanding? What are the precise effects of the decay on the individuals comprising the society? and How do these effects develop from the primary cause? For this a study of other societies in different stages of development is essential. Psychiatry is not too young for the task—it is simply too naive.

F. W. Hanley, M.D., Ottawa, Canada.

AGAINST EPONYMS

To the Editor:—I should like to call attention to an article in the Dec. 28, 1946 issue of The Journal, page 1070, entitled "Guillain-Barré Syndrome Treated with Neostigmine."

Comparatively few readers would know what the Guillain-Barré syndrome was, although most of us would know virus encephalomyelitis. Many of us would not bother reading about the Guillain-Barré syndrome since it would be completely foreign to us, while we would be highly interested to know about neostigmine treatment of such a common condition as virus encephalomyelitis. Thus perhaps valuable information would be missed because of personal name reference.

How much more interesting would it be if it read "Virus Encephalomyelitis Treated with Neostigmine." If it is really necessary to cater to the name of the man or men who first described a certain disease for reasons of stimulating people's interest or for reasons of good will, their name might be put in parentheses after the descriptive name rather than the reverse. I believe, however, that most medical men should be big enough to give to the profession their description of a new entity without requiring that their names be repeated and advertised whenever the disease entity is mentioned.

William Wolf, M.D., New York.

REMOVAL OF ODOR FROM BOOKS

To the Editor:—In The Journal of Nov. 9, 1946, in Queries and Minor Notes, page 609, there appeared an inquiry from Don A. Duffie, M.D., of Central Lake, Mich., on getting rid of the smell of books.

While mold is frequently present and is popularly charged with causing the odor from books, especially when the relative humidity of the air is high, there are other factors which contribute to book deterioration and the accompanying odor. One potent cause is sulfur dioxide, which is a common ingredient of the atmosphere and is in high concentration over cities.

This menace has been controlled by recirculating the air of the library through activated carbon. This method not only reduces the sulfur dioxide content to a negligible quantity but at the same time removes any extraneous odors from the air. The system has been applied successfully to the Rare Books Rooms of the Widener Memorial Library at Harvard and of the Sterling Memorial Library at Yale and to the Archives Vault of the State Museum at Denver, Colo.

MEDICAL JOURNALS NEEDED IN THE NETHERLANDS

To the Editor:—A friend of mine in the Netherlands to whom I have been sending various American magazines after I have read them asked me if I knew a doctor who would be willing to provide her son, a medical student, with old copies of THE JOURNAL. Instead, I sent a year's subscription to this young man, and I quote the letter of acknowledgment I have received from him:

> You cannot imagine how much I was surprised to hear from my mother that you intended to give me a year's subscription to THE JOURNAL. It is for a Dutch student in his third year a great sensation to get a journal which professors and doctors here try to get in vain. We have got a Dutch medical journal too but owing to the war it is not up to date and cannot be compared with the American ones. THE JOURNAL is even superior to the London *Lancet* and that's why so many medical people hanker after such an elaborate journal. I will of course share all the copies with my fellow students. After all these words I have forgotten to thank you but I think you will understand my gratitude.

Perhaps I should explain that because of the present currency controls in the Netherlands the Dutch cannot use their money to buy foreign exchange for anything but the vital necessities. Therefore many Dutch people who would be able and willing in normal times to pay for subscriptions to foreign publications cannot do so.

It occurs to me that many American doctors, if this was brought to their attention, would be more than happy to send subscriptions to doctors and students in the Netherlands. I am sure medical schools and medical associations in that country would be glad to furnish names or distribute the copies. Or some doctors might be willing to send their back files of THE JOURNAL for the war years.

The quoted letter makes it clear how gratefully your publication would be received and how generously it would be shared. As one who spent two of the war years in two European countries, I can testify to what a real privation it is to be denied access to current publications from abroad and how one longs for every contact with the outside world. I therefore hope that my fellow countrymen of the medical profession will find this suggestion good and respond to it.

MRS. C. A. TAYLOR.

NEUROLOGIC COMPLICATIONS OF SPINAL ANESTHESIA

To the Editor:—In connection with the paper of Drs. Nicholson and Eversole on "Neurologic Complications of Spinal Anesthesia" (THE JOURNAL, Nov. 23, 1946), the following case seen in an Army hospital in 1943 may be of interest:

A Negro aged 30 had undergone an appendectomy about three months prior to the time I saw him. The operation was performed under spinal anesthesia, and metycaine (dose unknown) was used. Because the anesthetic would not take, a second dose of the same drug was introduced into the spinal canal and the operation successfully completed. The postoperative course was complicated by a slowly improving cauda equina syndrome. There was a complete paralysis of the lower extremities for about three days; urinary difficulties were reduced to mere hesitancy by the time the patient came under my observation. Hyperreflexia and sensory changes also were present.

The interesting feature of this case was the presence of sexual impotence. The patient stated that he had noticed the absence of erections immediately after the operation. The patient attempted intercourse about a month after the operation but was unsuccessful. Two months later women were still "sore" at him because of his impotence, although occasionally he would be able to complete the act. A follow-up of this case was impossible because of the military situation.

A review of the literature available in 1943 was negative as far as the description of sexual impotence following spinal anesthesia was concerned. I do not know of any case with similar symptoms described in the literature since.

PERCY MASON, M.D., New York.

BLOOD GROUP TESTS OF THE NEWBORN

To the Editor:—In the December 7 issue of THE JOURNAL Dr. M. A. Hyman recommends blood group tests for identification of the newborn child. The suggestion is not practical, because it recommends testing for far too large a number of blood factors.

Testing serums for factor P are very rare, difficult to obtain and frequently not reliable. They are seldom used even by experts. Also very rare is testing serum for factor Hr. Testing serums for factors M and N are easily prepared, but tests for these factors are best carried out by expertly trained workers. Subgroups of A are frequently not clearly differentiated in the newborn. Subgroup A_2 may be mistaken for O and A_2B for B. Even experts recommend "in affiliation cases not to carry out the (grouping) tests until the child is at least one month of age" (Wiener, A. S.: Blood Groups and Transfusion, 1943, p. 386). Thus, it is likely that the tests for factors P and Hr and for subgroups A_1, A_2, A_1B, and A_2B would have to be excluded at time of birth in most instances.

However, with the reservations mentioned, Dr. Hyman's suggestion is worthy of consideration. Tests for the A, B, O and Rh factors would add to the reliability of identification of the newborn infant by footprints. The mother's blood factors should also be determined as part of the prenatal examination.

ISRAEL DAVIDSOHN, M.D., Chicago.

NUTRITION DURING PREGNANCY

To the Editor:—In reference to the note "Prevention of Congenital Malformation" (THE JOURNAL, November 16, p. 674), I should like to add that there is another factor which ought to be taken into consideration; it is the question of maternal nutrition during gestation. There was a paper written about three or four years ago on this subject by a group in Boston and their work seemed to indicate that this also plays a role. I remember that at the time the significance of the work was not appreciated and that many people concerned with this aspect of medicine remained uninformed.

H. G. KEITEL, Lieutenant, M. C., A. U. S.,
Station Hospital, Fort Hamilton, Brooklyn.

SUGGESTION FOR FIXING NASAL TUBE

To the Editor:—I am offering a suggestion for fastening the Levin nasal tube in place, which I consider simple and practical.

After the tube is passed the desired distance and wiped free of lubricant, a 2 foot length of 1 or 2 inch gauze roller bandage is placed parallel to the tube, with its midpoint just beneath the nostril. The bandage is fastened to this point on the tube by a few turns of ½ inch adhesive tape. The bandage is then knotted over the tape, and the free ends are brought across the face over the ears and tied in the suboccipital region, as in tying the strings of a surgical mask.

This method is comfortable and avoids slipping of adhesive tape which has been loosened by perspiration.

JEROME SCHROFF, M.D., Baton Rouge, La.

Medical Motion Pictures

FILM REVIEWS

A New Horizon. 16 mm. Black and white, sound, 750 feet (1 reel), showing time twenty-one minutes. *Produced in 1946 by RKO-Pathe, Inc.* Presented by and procurable from the National Foundation for Infantile Paralysis 120 Broadway, New York 5.

This is a dialogue propaganda film on physical medicine. The story opens with two interns arguing about the diagnosis of the condition of a patient whom they see at a distance. They consult an orthopedist, who says that the patient is his and gives a diagnosis of poliomyelitis. The orthopedist then turns the interns over to a specialist in physical medicine in the treatment of poliomyelitis and other diseases. Some of the initial dialogue between the specialist in physical medicine and the interns is good, but there are many weak points. After this initial discussion the physiatrist and the interns walk through a department of physical medicine and see various types of patients receiving different kinds of physical treatment. Discussion turns to a curative workshop, and there are flashbacks to show how simple equipment is employed to rehabilitate patients at this workshop. There is a final talk by the physiatrist in which he makes an emotional appeal to the interns to employ good physical treatment, and then the camera focuses on the Oath of Hippocrates as the film ends.

To the physician interested in physical medicine, this film is disappointing. In general the script is well conceived, but one regrets the numerous minor weaknesses which ruin it and defeat its purpose. Despite good camera technic and a good overall general plan, the physician-actors in this propaganda dialogue just do not speak the language of scientific physicians. The interns' naive and rather stupid argument concerning the diagnosis of the condition of a patient whom they have not even examined will immediately antagonize most physicians. This defeats the main purpose of the film, which is obviously to arouse the respect of members of the medical profession for this important field of medical practice. Also the main character, the physiatrist, is not well cast and does not give the proper impression of scientific ability, maturity and forcefulness. This film was obviously conceived in a laudable effort to tell physicians more about physical medicine, and it is to be regretted that so much fine effort has been completely spoiled by lack of appreciation of the average physician's reaction to a number of minor weaknesses. One has a distinct feeling of disappointment because this could have been such a good film but has turned out so poorly.

The film was shown to a group of physicians without comment, and all immediately expressed unfavorable reactions. Among the comments were "medically amateurish," "undignified," "unprofessional," "more like a soap opera than a scientific presentation," "too obviously propaganda" and "it antagonizes rather than wins the interest of the physician."

The film will harm, not help, the development of proper respect for physical medicine by physicians.

Anesthesia. 16 mm., Color, sound, 825 feet (1 reel), showing time twenty-three minutes. Produced in 1946 by Princeton Film Center, Princeton, N. J. Professional adviser, E. A. Rovenstine, M.D. Procurable on loan from Merck & Co., Inc., Rahway, N. J.

This is a report type film dealing particularly with Vinethene anesthesia rather than with the much broader subject suggested by the title. The photography is excellent. The pronunciation of Vinethene should be changed in the narration. The clear presentation of the chemical properties of Vinethene (divinyl ether) would be enhanced by the addition of a structural formula and a comparison of ethyl ether. The method of administration of Vinethene alone and in combination with ethyl ether or nitrous oxide-oxygen is demonstrated. Several dental extractions and brief otolaryngologic surgical operations are shown. The film would have greater teaching value if certain important points, such as indications and contraindications, signs and treatment of overdosage, were presented in a visual text rather than only mentioned in the narration. A more thorough demonstration and discussion of fewer operative procedures, including the necessity of preanesthetic examination of heart and lungs and urinalysis on every patient, the importance of maintaining a patent airway to prevent anoxia, a suction device at hand on all surgical operations in the mouth and upper air passages and examination of the circulatory, respiratory and eye activity during anesthesia, would make this a valuable teaching film for medical students, dentists, surgeons and anesthesiologists.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of Doctor's License for Commission of an Abortion.—The Board of Medical Examiners revoked the defendant's license to practice medicine on the ground that he had been guilty of performing an abortion, and the revocation was sustained by the trial court. Accordingly the defendant appealed to the district court of appeal, first district, division 1, California.

The defendant's first point, said the court, deserves scant attention. He argued that, because the accusation against him was made by an agent of the respondent medical board and said board heard the evidence and determined defendant to be guilty, the defendant was deprived of his valuable property right to practice medicine without due process of law. No authority is cited in support of this contention. Under our statutes, continued the court, the right to practice medicine is granted to all qualified persons by the respondent board and said board is likewise granted the right, and indeed charged with the duty, to hear and determine any accusations bearing on the qualifications of a licensee to continue the practice of medicine. If a physician whose license is ordered revoked by the board is not satisfied with the determination of the board, he may, as was done in the instant case, apply to the superior court for a review of the board's action, and he then may have a full and complete hearing in the superior court. Not only is he not deprived of a right of property without due process but he is given ample legal opportunity to protect that right.

Section 2377 of the Business and Professions Code, the section which the defendant was charged with violating, provides:

> The procuring or aiding or abetting or attempting or agreeing or offering to procure a criminal abortion constitutes unprofessional conduct within the meaning of this chapter.

A criminal abortion is defined by section 274 of the Penal Code as follows:

> Every person who provides, supplies or administers to any woman, or procures for any woman to take any medicine, drug or substance, or uses or employs any instrument or other means whatever, with intent thereby to procure the miscarriage of such woman, unless the same is necessary to preserve her life, is punishable by imprisonment in the state prison not less than two nor more than five years.

The defendant's principal contention was that the evidence was insufficient to sustain either the board's order or the judgment of the trial court. A detailed analysis of the evidence, said the court, is not necessary to demonstrate that the Board of Medical Examiners was justified in concluding that the defendant committed certain prohibited acts with intent to cause a miscarriage on the persons of Miss Ballard and Mrs. Palmer and that the superior court was justified in reaching the same conclusion on the same record. It is difficult to understand how any other conclusion could be reached. The evidence showed that the defendant knew that both women were pregnant when they visited him, and he admittedly performed the acts amounting to an abortion. The evidence also showed that both women were in normal health, except for being pregnant, that the performance of an abortion therefore was not necessary to save the life of either; also the defendant required each woman to sign a card which was later filled in to read that each had undergone an abortion prior to consulting the defendant. All essential elements of a criminal abortion were established, said the court, and the evidence abundantly sustains a violation of section 2377 of the Business and Professions Code. The proceeding here involved is an administrative, disciplinary proceeding and is not criminal in its nature nor is it to be judged by the legal standards applicable to criminal prosecutions. As stated in a prior case:

> Where, on the other hand, the legislature has created a professional board and has conferred upon it power to administer the provisions of a general regulatory plan governing the members of the profession, the overwhelming weight of authority has rejected any analogy which would require such a board to conduct its proceedings for the revocation of a license in accordance with theories developed in the field of criminal law. . . .

Finally the defendant argued that the evidence was insufficient because the 2 women involved were accomplices. The requirements of corroboration in a criminal case do not apply to administrative proceedings, said the court. This action not being criminal in its nature, it is apparent that the statutory mandate that a person may not be convicted on the uncorroborated testimony of an accomplice has no application here. We feel satisfied that any witness whose testimony as to competent facts was convincing to the board engaged in the hearing of the charge would be legally sufficient. We have already expressed the conclusion, the court said, that the testimony of persons who might be accomplices could be received and might be considered by the board trying the charge. Accordingly, the order of revocation entered by the Board of Medical Examiners and affirmed by the superior court was sustained.—*Murphy v. Board of Medical Examiners of California, 170 P. (2d) 510 (Calif., 1946).*

Abnormally Long Pregnancy Raises No Presumption of Infidelity.—The plaintiff's husband filed suit for divorce on the ground of adultery, the case being heard in the Supreme Court, special term, Queens County, New York.

The plaintiff and defendant were married on March 12, 1944. On April 24, 1944 the plaintiff, an officer in the merchant marine, left the country for duty in the Pacific, returning to the United States Jan. 4, 1945. On April 14, 1945 the defendant gave birth to a child which she claims is the child of the plaintiff. The plaintiff offered no evidence of any misconduct on the defendant's part but asked for a decree solely on the hypothesis that it is impossible for a period of 355 days to elapse between coition and parturition.

A gynecologist who taught at the Yale Medical School, called as an expert witness by the plaintiff, testified that the accepted period of gestation is 270 days, with the longest authenticated period being 320 days. He admitted that there was a nonauthenticated case of 369 days. A physician called by the defendant as an expert testified that the ordinary period of gestation is 280 days, or ten lunar months, but that there are instances of 328 days and 344 days.

The physician who attended the defendant during her pregnancy testified that the defendant came to her on Nov. 14, 1944, complaining of pain in the right side of the abdomen and said that she had previously had pain in the left side of the abdomen. The defendant informed the physician that her last menses was Oct. 4, 1944 and that the last time she had seen her husband was April 24, 1944. The physician advised her that the birth should take place about the end of January 1945. The defendant immediately wrote to her husband and informed his family as well as her own friends and family. On Feb. 5, 1945, when she examined the defendant, the physician said she found the head of the fetus engaged, a position of the head which generally occurs about a month prior to birth. In the light of this testimony, said the court, the birth should have occurred about March 5, 1945; which would have been 316 days from coition, a not improbable period of gestation. On Feb. 19, 1945, however, the physician again examined the defendant and, finding no sign of impending birth, recommended that the defendant go into a hospital. The defendant spent three days in a hospital, February 28, March 1 and March 2, during which time she received treatment to induce labor. These treatments were ineffectual, however, and the defendant returned to her home, finally giving birth to a 9 pound child on April 14, 1945. The physician stated that on every examination of the defendant the fetus was small.

It thus appears, said the court, that while the duration of pregnancy was 355 days, the head of the fetus was engaged for at least 68 days, which presents a question as to whether the last forty days were a part of the period of gestation proper or were due to difficulty in delivering the child.

In an English case decided in 1921, there was no evidence of misconduct on the part of the wife except the lapse of time between coition and the birth of the child, which was 331 days. Three leading medical authorities testified that such an interval could not be said to be impossible. Viscount Birkenhead in dismissing the petition said:

> In this case the only evidence of adultery is the admittedly abnormal length of pregnancy. No other fact or circumstance has been adduced which in the slightest degree casts any reflection upon the chastity or modesty of the respondent, who has on oath denied the alleged adultery. I can only find her guilty if I come to the conclusion that it is impossible, having regard to the present state of medical knowledge and belief, that the petitioner can be the father of the child. The expert evidence renders it manifest that there is no such impossibility. Under these circumstances I accept the evidence of the respondent and find that she had not committed adultery, and accordingly I dismiss the petition.

The New York court said that the presumption of legitimacy is one of the strongest and most persuasive known to the law. Even aside from this presumption, however, having regard to the evidence in this case and the present state of medical knowledge and belief, it cannot be said that it is impossible that the plaintiff is the father of this child. The expert evidence, plus the fact that the head of the fetus was engaged for 68 days when birth normally occurs within a month after such engagement, "renders it manifest that there is no such impossibility." The court accordingly rendered judgment in favor of the defendant and dismissed the complaint.—*Lockwood v. Lockwood, 62 N. Y. S. (2d) 910 (N. Y., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal, Jan. 25, page 267.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part III.* Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

American Board of Dermatology and Syphilology: *Written.* Various centers, March 24. Final date for filing application is Feb. 17. *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: *Written.* Chicago, March 17. *Oral.* Chicago, April 24-26. Final date for filing application is Feb. 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

American Board of Neurological Surgery. *Oral.* Examination to be given during the Summer. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

American Board of Obstetrics and Gynecology: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Ophthalmology: *Oral. All Groups. Parts I and II.* Chicago, October. Final date for filing application is March 1. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Me.

American Board of Otolaryngology: *Oral.* St. Louis, April 16-20. Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

American Board of Pathology: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

American Board of Pediatrics: Effective May 1, application fee will be $125.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Toxicity of Mercurial Diuretics Observations on Eighteen Cases with Suggestions for Prevention of Toxic Reactions S Ben Asher.—p 711

Electrocardiographic Changes. — Coincidentally with the increased application of electrocardiography, there has developed a tendency toward misuse of this method, due to the fact that its limitations have not been recognized. It is of value in the recognition of the cardiac arrhythmias and in the detection of myocardial infarction. It may be useful in determining if and when the heart has become involved during certain systemic diseases and in determining whether or not a person has been taking certain drugs, notably digitalis but also various malarial drugs, epinephrine, ergotamine tartrate, atropine, emetine, tobacco smoke and so on The accepted standards of normality for the electrocardiogram are incorrect, since too many healthy young adults show changes which, according to these standards, are diagnostic of heart disease. Conditions not due to primary disease of the heart that may be associated with changes in the electrocardiogram similar to those caused by coronary sclerosis and myocardial disease include: acute infections, pericarditis, metabolic disorders, renal disease, acute manifestation of upper abdominal disease, pulmonary embolism and imbalance of the autonomic nervous system. Exercise may also cause changes in the electrocardiogram. The major cause for the more serious mistakes in interpretation is the widespread belief that changes in the QRST complex and especially the ST segments and T waves are specific for myocardial disease.

Toxicity of Mercurial Diuretics. — Ben-Asher reports reactions to mercurial diuretics in 18 cases, in 10 of which the reaction was delayed and was the result of dehydration This type of reaction was associated with a high environmental temperature. Nine of these patients recovered with the administration of salt and water. In 8 cases the reaction occurred immediately after the injection. An immediate reaction in a patient under dehydration therapy indicates a poor prognosis Reactions may be avoided by intermittent injections. Because excessive dehydration may follow diuresis and since chlorides may be lost through the sweat glands the mercurials should not be given during high environmental temperatures.

*Burn Shock Its Treatment with Continuous Hypodermoclysis of Isotonic Solution of Sodium Chloride into Burned Areas· Clinical Studies in 2 Cases J. K Berman, G. S. Pierce and M. M Best —p 577
Cysts of Duodenum R J Booher and G T. Pack —p 588.

Surgical Treatment of Patent Ductus Arteriosus.—Five patients whose ages varied between 18 and 30 years were operated on for patent ductus arteriosus The ductus of 2 patients was doubly ligated, of 2 patients it was severed between clamps and the ends oversewn, and of 1 patient it was plicated Bradshaw and his associates think that division of the patent ductus should be the procedure of choice when possible. One patient died Four had subacute bacterial endarteritis complicating their congenital heart disease. These 4 patients had preoperative embolic accidents. The mediastinal pleura of the last 3 patients was closed, since it was felt that the area was sterile as the result of the penicillin therapy. Penicillin has materially aided in reducing the mortality rate of patients with subacute bacterial endocarditis superimposed on a congenital patent ductus arteriosus

Treatment of Burn Shock with Hypodermoclysis of Isotonic Solution of Sodium Chloride.—Berman and his associates report observations on 2 patients treated with this method. One of these patients died and the other survived They stress that this treatment of burn shock is useful in neutralizing or diluting hypothetic toxins, as illustrated in the patient whose burn toxemia was adequately controlled. In the patient who died it was at least partially neutralized. The patient who died had an alkalosis which may have been due to an excess of sodium. A warning is sounded concerning excessive administration of sodium and fluid. Even though the fluid is given subcutaneously or by mouth, it is believed that in the late stages of burn toxemia slight underhydration is safer than overhydration, and acidosis is more easily controlled than alkalosis. The authors conclude that the use of isotonic solution of sodium chloride by continuous hypodermoclysis into the burned area is to be recommended in extensive burns for burn shock and toxemia. It is useful during the granulation stage of burn wounds to increase resistance to infection and to stimulate healthy granulation tissue..

Blood Groups, Subgroups and Rh Factor of Mapuche Indians of Province of Cautin, Chile. L. Sandoval S., C. Henckel and L. Givovich.—p. 555.

Storage of Human Plasma in the Liquid State.—Analysis of 3,384 questionnaires completed after administration of liquid plasma more than a year old indicates that the transfusion of such plasma is safe and beneficial up to at least three years of storage. The untoward reaction rate following these administrations was significantly less than that following a comparable series of 1,500 administrations of commercially prepared dried plasma. The chemical and physicochemical changes observed in plasma stored in the liquid state at room temperature are of no more clinical significance at the end of three years' storage than at the end of eighteen months, the present National Institute of Health expiration date. Because at the end of six months' storage liquid plasma is devoid of blood coagulation factors, complementary activity and probably other antibodies, it should not be administered to patients with either hemorrhagic diatheses or infections and who require these components specifically. Hence it should be used chiefly for its colloid content and should be subject to the same precautions regarding excessive dosage as is human serum albumin.

Pseudohemophilia.—A condition which is often hereditary and is characterized chiefly by a prolonged bleeding time in the presence of normal platelets is referred to as "pseudohemophilia" or "hereditary hemorrhagic thrombasthenia." Perkins presents the history of a patient with this condition, which was transmitted by and occurred only in the male line. The occurrence in the male offspring of the patient's father and of the latter's second wife irrefutably proves this point. The degree of prolongation of the bleeding time varied from day to day and was occasionally normal. Except for transient hypocalcemia with tetany, no defect in the blood elements or in clot formation was noted. There appears to be a failure of normal capillary constriction following trauma.

Recurrent Dislocation of First Carpometacarpal Joint Repaired by Functional Tenodesis. O. C. Kestler.—p. 858.

Management of Penetrating Wounds of Knee Joint.—Hampton says that no sepsis of the knee joints was observed in patients treated with complete initial surgery, closure of the synovial membrane or capsule of the joint, and adequate immobilization. Suppurative arthritis with prolonged drainage and slow destruction of the articular surfaces was observed in several patients whose joints had moderate or even minimum intra-articular damage but in whom the excisional surgery had been poor and the joints had been left open for drainage. An aggressive surgical regimen was instituted in the 19 patients under close observation. Eight knee joints in which there had been only minimum exposure at the time of the initial operation were reopened. In 4, devitalized areas of articular cartilage were removed. After irrigation the joints were closed, penicillin was instilled and immobilization was provided. No suppurative arthritis followed. Six knee joints with suppurative arthritis, but without septic destruction of the joint, were opened widely. The joint was cleaned; blood clot and pus were removed by irrigation. The synovial membrane was sutured. Penicillin was instilled and immobilization was provided. Aspiration, irrigation and reinstillation of penicillin were performed at intervals of twenty-four or forty-eight hours for about a week. The sepsis was controlled. Subacute septic processes in 2 other knee joints also were treated surgically. Limb endangering sepsis in 3 knee joints was eradicated by resection of the joint. The authors stress that the initial surgical treatment should include arthrotomy, excision of the devitalized tissue, cleansing of the blood clot and débris from the joint, suture of the synovial membrane or capsule and immobilization of the limb. At reparative surgery, preferably from five to ten days after the intra-articular surgery, the skin should be sutured. In cases of suppurative arthritis the same surgical plan is indicated. Systemic penicillin supplemented by the local instillation of penicillin into the joint should be employed in patients with wounds and suppurative arthritis of the knee joint.

Reinforcement Bone Grafts.—According to Carpenter and his associates the condition called limited union is not to be confused with delayed union. Delayed union progresses to solid bony union in due time, and the end result is compatible with normal function. Limited union is a condition of solid bony union; but the end result is a shaft which is incapable of normal function, since it is weaker and usually smaller than normal The authors delay a bone graft operation until three months after complete wound healing in order to minimize the incidence of infection The extent of bone healing at this time will nearly always indicate whether the fracture will progress to a complete and sufficient union by conservative measures. The authors performed a total of 52 reinforcement bone grafts for limited unions The bones requiring operation were the femur, tibia, first metatarsal, humerus, ulna and radius. Tibial grafts with multiple chips and cancellous bone from the upper tibia were used in most cases. Iliac grafts may be used advantageously. As a general rule, screws are used to fix the graft and plaster casts for external fixation, except for the femur, which is almost always treated in suspension-traction

Paget's Disease.—Newman in reviewing the case records at the Hospital of the University of Pennsylvania for a fifteen year period found 82 cases of Paget's disease in a total of about 127,000 histories The disease shows about an equal distribution between the sexes. It occurs predominantly in late middle life. Only 29 patients entered hospitals because of pain in a part of the body where the bones were found to show pagetoid changes Two patients complained chiefly of deformity, and 8 others had complaints related to cranial nerves in areas found to have pagetoid changes. In over 50 per cent of the cases, Paget's disease was an incidental finding The pelvis was involved in 29 cases, the skull in 25, the spine in 16, the femur in 17, the tibia in 7, the humerus in 2 and the radius, fibula and metacarpals each in 1 case The complications of Paget's disease are cranial nerve pressure, fractures, urinary calculi and sarcomatous degeneration It is the complications of Paget's disease which usually cause the patient to seek medical care. Of the treatments directed against the symptoms of the disease as such the author mentions only roentgen therapy and magnesium carbonate

Influenza Index.—Schwartz and his associates propose a serologic index for the study of influenza, the use of a spectrophotometer for facilitating the estimation of hemagglutinin and antibody titers, and a simplified method of calculating hemagglutinin and antibody titers. They studied the antibody levels of the civilian and military population of Oahu following an epidemic of influenza B and during a period of mass vaccination carried on by the army. The index demonstrated the generally elevated level of influenzal antibody titer just after an epidemic, and the subsequent decline of that titer. The general antibody response to mass vaccination and the comparative antigenic effectiveness of the PR 8 and Lee components of the vaccine were demonstrated. The study also indicated an antigenic difference between the Lee strain of influenza B and a local strain of influenza B isolated during a recent epidemic.

Attenuation of Virulence with Retention of Antigenicity of Mumps Virus.—Enders and his co-workers found that after twenty-five serial passages in the embryonated egg the virus of mumps loses its capacity to induce typical experimental parotitis in the monkey when inoculated via Stensen's duct. Such attenuated virus immunizes the monkey against a subsequent inoculation of the agent in its virulent form The attenuated virus likewise induces the formation of complement fixing antibody and the factor which inhibits hemoagglutination There is evidence that the complement fixing antibody and the antihemoagglutinin are not identical. Mumps virus after twenty-five passages in the chick embryo appears to be no longer capable of inducing typical mumps in presumptively susceptible human beings when sprayed into the oral cavity. It may, however, irregularly lead to the formation of complement fixing antibody. The results of an experiment in 1 child suggest that the virus after a single egg passage may provide a more satisfactory immunizing agent.

*Synergism Between Barbiturates and Ethyl Alcohol. Helen Ramsey and H B Haag—p. 313.

Synergism Between Barbiturates and Alcohol.—Ramsey and Haag found that when sodium seconal was given orally to mice the lethal dose was considerably lowered when alcohol was given at the same time The anesthetic dose of sodium pentothal for dogs was also reduced by previous oral administration of 95 per cent alcohol Duration of anesthesia resulting from sodium pentothal injection was greatly increased in the presence of alcohol The onset of anesthesia from injection of sodium barbital appeared to be delayed by the presence of alcohol, but the duration of anesthesia resulting from the injection of sodium barbital was materially increased by the presence of alcohol The blood level of sodium barbital was not altered by the presence of alcohol. Picrotoxin was found less efficient as an analeptic in rabbits given sodium pentobarbital plus alcohol than in those given sodium pentobarbital alone.

Colloid Carcinoma of Gallbladder, with Widespread Metastases.—p. 691.
Fibrous Dysplasia of Rib.—p. 693.

Endometriosis.—Fallon and his associates state that the diagnosis of endometriosis is oftener missed than made. They report 200 cases of external endometriosis, of which only 6 had entered the clinic with a correct diagnosis. During a period in which 107 cases of microscopically verified endometriosis were observed, only 78 cases of appendicitis were encountered in female patients; that is, endometriosis is more frequent than appendicitis. Endometriosis is a new growth of menstruating endometrium that, invading and sometimes metastasizing, tends to spread through the pelvis, causing chemical peritonitis, dense adhesions, sterility, destruction of ovaries and stricture of the pelvic intestine. The course, which is reversed by ovarian deactivation, may be arrested by excision of the lesions. To arrest without castration necessitates diagnosis before the lesions have become unresectable. The basic syndrome of endometriosis is cumulatively increasing pain at the time of the period occurring after about five years of menstruation without pregnancy. The prophylaxis seems to be early marriage and a child every few years.

Streptomycin in Meningitis Due to Friedländer's Bacillus.—Tartakoff and his associates report that a man from whom a meningioma was removed from the right hemisphere in the frontal area was diagnosed a week later as having meningitis, and Friedländer's bacillus type B was demonstrated in cultures of the blood and the spinal fluid. In spite of continued intramuscular and intrathecal penicillin, supplemented by sulfadiazine, the patient's condition became worse and although the spinal fluid showed no organisms it became increasingly gelatinous. Intrasternal administration of streptomycin was begun, but the man died three days later. It is significant that after the administration of streptomycin the spinal fluid became less viscid and that at necropsy study of the meninges and of the surface of the brain disclosed evidence of a nearly healed meningitis. Whether this would have been found if only the use of penicillin had been continued cannot be answered. Death was due to pulmonary embolism incident to a thrombophlebitis in the lower extremities.

Syncope as a Diagnostic Problem.—For purposes of differential diagnosis Brian divides the mechanisms producing syncope into four fairly well defined groups: cardiovascular, endocrine, neurogenic and psychogenic. Unconsciousness resulting from cardiovascular disorders is, as a rule, due to a sudden transitory diminution or cessation of cerebral blood flow. Metabolic disturbances may result in sudden loss of consciousness by producing hypoglycemia or lowering of the blood pressure, or both. Psychogenic and neurogenic fainting results from psychoneurotic and neurologic disturbances respectively. The latter is due to suddenly changing intracranial pressure and an associated variation in the cerebral arterial circulation.

Blood Bilirubin in Differentiation of Peptic Ulcer and Portal Cirrhosis.—Seven cases of massive gastric hemorrhage resulting in profuse hematemesis form the basis of this report by Navarro and his associates. Four of these patients had peptic ulcer and the other 3 had portal cirrhosis. The patients with peptic ulcer showed practically no bilirubin in the blood, while those with portal cirrhosis showed significant amounts of bilirubin. When clinical, laboratory or x-ray findings are not sufficiently distinct in cases of massive gastric hemorrhage, the bilirubin content of the blood may help in the differentiation of these two conditions.

Carcinoma of the Colon.—Ochsner and Hines review observations in 113 cases of carcinoma of the colon in 45 of which there was evidence of extension. The resectability of lesions in the right colon and those of the rectosigmoid were approximately the same, 81.8 and 84.3 per cent respectively. Lesions of the left colon, exclusive of the rectosigmoid and rectum, had a much lower incidence of resectability (65 per cent). The authors stress that the curative treatment of malignant lesions of the colon consists in wide removal of the involved portion of the bowel and the possible sites of metastasis. Although reestablishment of the continuity of the bowel in low-lying lesions has become quite popular, the authors believe that in any lesions except the extremely small ones in which there can be no extension distally abdominoperineal resection is the operation of choice and that as long as attempts are made to preserve the sphincter the recurrence rate and death rate from carcinoma will continue to be high.

Deposition of Mercury in the Eye.—Abramowicz reports the experience of a woman aged 57 who requested the removal of dark pigmentation of the eyelids of both eyes. At the age of 16 she had had "blepharitis" and from that time on, in fear of a relapse, she continued to employ a remedy nearly every night. Now she was asking for the removal of the pigmentation which appeared about ten years ago and gives her much trouble because of resemblance to an exaggerated makeup. Examination revealed deposition of mercury in the eyelids, the bulbar conjunctiva, the region of Descemet's membrane and the anterior lens capsule.

Tetraethyl Lead Poisoning.—Tetraethyl lead is the active ingredient of ethyl fluid, an anti-knock compound. Cassells and Dodds are concerned with the hazard involved in the cleaning of storage tanks which have contained leaded gasoline. After the cessation of hostilities a number of tanks which had been constructed for war purposes were no longer required. The regulations governing the cleaning procedure were overlooked or disobeyed in some instances, with the result that 25 cases of poisoning occurred, 2 of which were fatal. The earliest symptoms were disturbance of sleep and symptoms referable to the alimentary tract, such as lack of appetite, nausea, vomiting and diarrhea. Subjective nervous symptoms were irritability, restlessness, nervousness and anxiety. Pallor was not a feature, nor did punctate basophilia appear. If death does not occur, recovery is usually complete. All that is necessary in the milder cases is removal from exposure, light exercise in the open air, a normal diet with plenty of fluids, and the relief of sleeplessness by a suitable sedative. The treatment of the severe case calls for strict nursing supervision in view of the impulsive suicidal tendencies and the need for adequate fluid intake and sedation.

Jaundice After Penicillin Treatment.—Hughes found that of 124 patients with hepatitis treated in a military hospital in India 36 had had penicillin treatment. He thinks that this condition is transmitted from patient to patient by means of contaminated syringes. Experiments are described which show that a single intramuscular injection of 1 cc. of fluid may lead to contamination of the syringe used. The mechanism by which this contamination occurs is discussed.

Lactic Acid Injection in Osteoarthritis.—Stimulated by the work of Waugh on intra-articular injection of lactic acid with procaine into the hip, Mawson recently gave his treatment to 26 patients. From 15 to 20 cc. of a stable solution of 0.2 per cent lactic acid with procaine having a hydrogen ion concentration of 5.2 is injected into and around the hip joint on each occasion. A similar amount may be injected into the knee joint, but the wrist joint will only take amounts varying from 2 to 5 cc. After the injection the patient has to put the joint through all its movements. Two days of bed rest is prescribed. A second injection is given after seven days. Subsequent injections up to six are given if needed. All the 6 wage earners were able to return to work. Of the remaining 20, who were mostly housewives, 18 experienced considerable relief.

*Salt Deficiency in Sprue. D. A. K. Black.—p. 671.
Myocardial Fibrosis Following Arsenical Therapy: Report of Case. J. R. Edge.—p. 675.

Concentrated Plasma in Traumatic Pulmonary Edema.—According to Cleland pulmonary edema due to trauma is observed in burns due to underground explosions in mines, in gasoline explosions, in accidental inhalation of noxious gases in industry and in accidental overtransfusion. On the basis of illustrative cases he shows that intravenous concentrated plasma has seemed to be a valuable addition in the treatment of pulmonary edema due to trauma. There has been no tendency for the pulmonary edema to recur after this treatment. Apart from the risk of reactions to the plasma, the method is dangerous only if applied without preliminary venesection in cases of pulmonary edema due to overtransfusion.

Salt Deficiency in Sprue.—The 10 patients investigated by Black were selected from several hundred with sprue. The basis of selection was low blood pressure with asthenia, and signs of peripheral circulatory failure. The patients had low serum sodium and serum chloride levels and in some cases a plasma volume which was low in relation to body weight. When the patient was put on a high intake of salt, sodium and chloride were both retained, and the serum sodium and serum chloride rose to normal levels; the blood pressure rose and clinical signs of dehydration disappeared, though the abnormal loss of fat in the stools was not affected. Loss of electrolyte in copious watery stools is thought to be the main cause of the salt deficiency, but diminished intake of salt in anorexic patients is also a factor. The results reported do not suggest adrenal insufficiency. Treatment by increasing the salt intake to 15 Gm. a day corrects the dehydration in a few days.

Toxic Goiter in the Middle Aged and Elderly.—Thyrotoxicosis is a relatively common disease in the middle aged and elderly and may be present without a visible goiter or eye signs, and tachycardia may be minimal. Nearly all patients lose weight and are a little tremulous and weak. They tend to have high pulse pressures and hypertension and are usually breathless. The importance of early diagnosis and treatment is stressed, because degenerative cardiovascular changes tend to be accelerated by the condition.

Industrial Fluorosis.—Green says that, during the calcining of ironstone, smoke drifts on to neighboring farms, and on the nearest of these an obscure disease of cattle was reported. Samples of urine established a diagnosis by revealing 26 to 69 parts per million of fluorine. Samples of water from the affected farm showed only 0.5 part per million of fluorine, but grass samples within a few hundred yards of the burning mounds showed over 2,000 parts per million on the dry matter. The urine of the human family on the farm showed 1.3 to 4.2 parts per million of fluorine, thus averaging less than one-tenth that of the cattle urines but nevertheless being above normal and far above the value in the drinking water. Surface contamination of green vegetables is suggested as the source.

*Aminothiazole (2921 RP) in Treatment of Toxic Diffuse Goiter. M. Perrault.—p. 401.
Prophylaxis of Acute Poliomyelitis. J. Pignot.—p. 410.

Treatment of Toxic Diffuse Goiter.—Perrault administered the French synthetic antithyroid agent aminothiazole (abadol) to 129 patients with toxic diffuse goiter, 0.4 Gm. being given in equally divided tablets of 0.1 Gm. four times daily. There were a few untoward reactions within the first two weeks of treatment in 15 cases (11.6 per cent), drug fever in 7, erythema in 3, urticaria in 1, nausea in 2 and backache with oliguria in 2. Simultaneous administration of amidonicotinic acid and occasionally of sodium hyposulfite or magnesia will prevent these untoward reactions. Aminothiazole is the treatment of choice in thyrotoxic cases of medium severity; it is indispensable in the preoperative treatment in severe cases, and it may be of the same value as iodine therapy in the mild cases.

Cavity of Apex of Lower Lobe: Clinical and Roentgenologic Features and Collapse Therapy. Y. Hebraud.—p. 573.

Electrocardiography in Malignant Diphtheria.—Giraud and his associates studied the electrocardiographic alterations in 33 patients with malignant diphtheria. Sinus tachycardia occurred frequently at the onset of the disease. In 12 cases auriculoventricular dissociation was observed from the fourth to the twelfth day of the disease, and a rapid ventricular rhythm with more than sixty and up to eighty and one hundred contractions per minute was observed in 11 of these cases. Paroxysmal ventricular tachycardia characterized the terminal period of the disease. Interauricular dissociation was observed in 2 cases with one series of positive P waves after a normal PR interval and with a second series of negative P waves maintaining a regular rhythm. In the great majority of the cases the alterations in the electrocardiogram occurred from the fifth to the twelfth day, but in some toxic cases death occurred in the absence of decisive alterations. A latent period precedes the appearance of definite anomalies, but in even less fulminating cases death may occur in the stage of branch block with only minor alterations in the electrocardiogram. Serial electrocardiographic studies should be made daily in the course of malignant diphtheria because of the changeable and transitory character of the graphic alterations.

Iron in Blood of Patients with Icterus and Anemia. P. Rambert, A. Morel, J. Boissier and R. Negri.—p. 1617.

Coagulating Property of Blood of a Hemophiliac.—Chevallier and his co-workers determined the coagulating property of the plasma and the serum of a hemophiliac in the presence of an excess of calcium and in a medium deficient in calcium. Complete absence of the coagulating property of the plasma and the serum of the hemophiliac was noted in a medium deficient in calcium. In the presence of an excess of calcium there was an initial absence of coagulating effect of the plasma and the serum of the hemophiliac for about thirty minutes. This was followed by a slow increase in coagulation. The coagulating property of the plasma and serum of the hemophiliac is considerably less than that of a normal person. There is a considerable delay in the appearance of the soluble thromboplastin in the extravasated plasma of a hemophiliac and an absence of free thrombin. Ultramicroscopic and photographic studies of the coagulum of the hemophiliac showed that its structure differs from that of a normal person. The specific structure of hemophilic fibrinous coagulum is closely related to the absence of free thrombin, which is absorbed by the hemophilic fibrin. The serum of a hemophiliac is rich only in free active prothrombin and its coagulating power in the presence of calcium appears almost equal to that of the normal serum. In vitro studies of the plasma of the hemophiliac showed that occasionally the clot undergoes considerable retraction and that most frequently the clot retraction is superior to that of the normal plasma.

Diuresis and Diuretics. O. Spühler.—p. 824.

Action Mechanism of Epinephrine.—Staub made determinations of the histamine content of the blood of human subjects following the intravenous administration of from 0.1 to 0.2 mg. of epinephrine, that is, of doses used therapeutically. It was found that the increase in histamine already begins during the injection of epinephrine, reaches its maximum at the end of the injection and rapidly decreases to normal values. Simultaneous determination of blood pressure, pulse frequency and leukocyte number reveals a time relation between decrease in blood pressure and maximum histaminemia. The 2 persons who had the highest increase in plasma histamine had also the most severe subjective disturbances, such as palpitation, anxiety and a feeling of weakness, so that these may be ascribed to the action of histamine. The author considers it probable that epinephrine vasoconstriction leads to reactive histamine discharge into the periphery and thus counteracts toxic epinephrine effects. He thinks that manifestations of collapse following conduction and infiltration anesthesia may be due to the effect of histamine. Undesirable side effects of epinephrine during local anesthesia might be counteracted by antihistamine substances.

Nutrition in Switzerland During the War.—Observations made on the 4 million inhabitants of Switzerland during the six war years show, says Fleisch, that the large amounts of calories, proteins and fat formerly considered as the optimum and which were eaten in such countries as the United States, England and Switzerland are not necessary. They probably do not represent the optimum for health. Whereas the League of Nations designates 2,400 calories as the standard for an adult not engaged in manual labor, Swiss observations indicate that 2,160 calories is sufficient. The standard of 1 Gm. of protein and 1 Gm. of fat per kilogram of weight seems adequate. A part of the meat and eggs eaten before the war and a large part of the cooking fats, sugar, white bread and macaroni can be replaced with good effects on the health by potatoes, vegetables, fruit and dark bread. From 75 to 90 per cent of calories are lost for human consumption if wheat is used to feed fowl and corn or barley as fodder for meat producing animals.

Giornale di Medicina, Palermo

3:95-138 (March-April) 1946. **Partial Index**

*Large Embolism in Bacterial Endocarditis in Course of Penicillin Therapy. G. Fradà.—p. 95.

Large Embolism in Penicillin Therapy in Bacterial Endocarditis.—Fradà directs attention to the frequency of embolism of the large blood vessels occurring in the course of penicillin therapy in acute and subacute bacterial endocarditis. Embolism of the large blood vessels took place in 4 of his 8 patients with acute or subacute bacterial endocarditis in the course of penicillin therapy. It occurred on the second or third day of the treatment. Embolism of the abdominal aorta took place in 1 case, in the femoral artery in 2 cases and in the axillary artery in 1 case. The author believes that penicillin increases coagulability of the blood and diminishes the resistance of the pathologic segments of the endocardium with consequent formation of thrombi. Liberal administration of papaverine and vitamin PP was without effect in the author's 3 cases.

*Cancer of Apex of Lung and Tumor of Superior Pulmonary Sulcus (Pancoast Tumor). O. Wichtl.—p. 228.

Apical Lung Cancer and Tumor of Superior Pulmonary Sulcus.—Among the necropsy reports of 10,209 patients who had been admitted to the Emperor Francis-Joseph Hospital in Vienna during the decade of 1933 to 1942, Wichtl found 302 reports of bronchial cancer, 43 with peripheral localization. Twelve of the latter group were to be considered as tumors of the apex of the lung, and only 2 of these were "Pancoast tumors." Microscopic studies suggest that the occurrence of cancer may be favored by tuberculous changes, which are frequently observed at this site, while Pancoast's concept that the tumor may arise from some embryonal rest is repudiated. The involvement of the superior pulmonary sulcus is explained by the restricted space within the thoracic cupola.

Combined Degeneration of Posterior and Lateral Columns in Hypochromic Anemia with Gastric Achylia. A. Verjaal.—p. 1076.

Mycosis Fungoides.—Lommen reports the history of a woman with mycosis fungoides who has been free from relapse for over twenty-two years. The author feels justified in reporting this case since he was unable to find in the literature of the last twenty years any other report indicating such a prolonged cure in mycosis fungoides. This result was obtained with prolonged roentgen therapy.

Acta Dermato-Venereologica, Stockholm

26:489-580 (May) 1946

Congenital Familial Anhidrosis and Neurolabyrinthitis.—Helweg-Larsen and Ludvigsen describe a Swedish family in which 14 members were suffering from congenital anhidrosis (intensified hypohidrosis). Diminished sweat secretion was noticed in the affected members of the family from the age of 1 year. Instead of sweat drops, granular or ring-formed salt formation appeared on the skin, being most conspicuous on the ridge of the nose, on the upper part of the neck and in the axillas. Subjectively the patients felt uncomfortable in the heat, and in summer they had to quit work on account of a sensation of heat, oppressive headache, dyspnea and palpitation. Biopsy of the right forearm showed absence of sweat glands or excretory ducts of sweat glands. On exposure to a temperature of 127.4 F. (53 C.) for fifty minutes large and very scattered sweat points appeared, most of them localized in the axilla and in the pectoral region; these spots gradually presented a ringlike appearance. Biopsy of the skin revealed a single, definitely hypertrophic sweat gland with high columnar epithelium corresponding to one of the annular sweat marks in the axillary fold. The patients did not present any dental anomalies, defective development of hair, ozena or cranial deformities. Neurolabyrinthitis occurred in these patients between the ages of 35 and 45 years. Because of the ectodermal origin of the labyrinth, the possibility of a common disposition to the labyrinthitis and anhidrosis is to be considered. In contrast to hypotrichotic anhidrosis, the anhidrosis in the authors' cases was transmitted by simple dominant inheritance. An autosomal morbid factor different from that for hypotrophic anhidrosis is suggested which may have a pleiotropic effect on the development of the sweat glands and labyrinths.

Book Notices

A Bibliography of Infantile Paralysis 1789-1944, with Selected Abstracts and Annotations. Edited by Morris Fishbein, M.D., Editor, Journal of the American Medical Association. Compiled by Ludvig Hektoen, M.D., Chief Editor, Archives of Pathology, and Ella M. Salmonsen, Medical Reference Librarian, John Crerar Library, Chicago. Prepared under direction of The National Foundation for Infantile Paralysis, Inc. Fabrikoid. Price, $15. Pp. 672. Philadelphia, London & Montreal: J. B. Lippincott Company, 1946.

Beginning with Underwood's clinical description of infantile paralysis in 1789, this book records the growth of our knowledge of the disease in all its aspects—clinical, pathologic, epidemiologic, microbic and therapeutic—year by year to the end of 1944. It would be a mistake, however, to infer from this statement that infantile paralysis did not exist before Underwood's time, as references are listed to writings dealing with evidence that cases occurred even away back in ancient times. One interesting omission deserves mention, namely the description by Charles Bell in 1836 of an epidemic fever with paralysis in children on the island of St. Helena. This appears to be the earliest outbreak of infantile paralysis as now known. The use of the bibliography is facilitated by a comprehensive subject index of the articles and other writings by number. Extensive use of the book confirms the statement in the preface that this arrangement is the most convenient of the methods used in large bibliographies. The subject index takes up about one sixth of the volume. There is a separate index by numbers of authors. In all the bibliography lists 8,320 items, but many items refer to more than one article. As a rule little or no attention has been given to textbooks, medical systems, encyclopedias and routine official publications. The style is consistently that of the *Quarterly Cumulative Index Medicus* but without inclusive pagination. The annotations and abstracts are in general clear, concise and factual. The work of the publisher has been very well done. The items are well spaced on the pages, and the print is easily read. The steady growth of the scientific and practical concern with infantile paralysis is well shown by the fact that according to the number of items the first half of the bibliography covers the years 1789 to 1927. Unfortunately the medical literature of the war years outside of America and Great Britain has not been freely accessible, but this defect as well as omissions and mistakes are to be made good in supplementary publications. The bibliography will lighten greatly the search in the literature on infantile paralysis.

Fundamental Patterns of Maladjustment: The Dynamics of Their Origin. A Statistical Analysis Based upon Five Hundred Case Records of Children Examined at the Michigan Child Guidance Institute. By Lester Eugene Hewitt, Lt. U. S. Army, and Richard L. Jenkins, M.D., Associate Professor of Psychiatry, College of Medicine, University of Illinois, Chicago. Cloth. Pp. 110. Springfield, Illinois: State of Illinois, 1946.

This report is based on the hypothesis that "children who differ from each other in expressing fundamentally different patterns of behavior maladjustment (which, for them, however, are rational patterns of adjustment to the situations which they have experienced) must have experienced fundamentally different patterns of environmental circumstances."

After a brief but illuminating review of previous studies in the field, the authors outline their methods of classifying their data in preparation for statistical treatment—largely by tetrachoric correlation without the calculation of probable errors. Three behavior syndromes were initially postulated and then in general confirmed by the analysis as follows: "(1) assaultive tendencies, temper displays, bullying vengefulness, defiance of authority, etc. (designated as the unsocialized aggressive behavior syndrome); (2) gang activities, cooperative stealing, aggressive stealing, staying out late nights, truancy from school, etc. (socialized delinquency syndrome); (3) sensitiveness, seclusiveness, shyness, cowardness, jealousy, etc. (overinhibited syndrome)." The first of these patterns was found to be most closely correlated with "parental rejection," the second with early "negligence and exposure," the third with family repression and physical deficiency (table XLI, p. 68). Under therapy, the nature of which is not specified, "the unsocialized delinquent showed the least tendency to change. The socialized delinquent showed either improved adjustment or intensification of the problem. The tendency to improvement in school adjustment was greater than that in the home or community adjustment. The best results were obtained with the overinhibited children with improvement the rule" (p. 78).

A psychiatric interpretation of these findings is given in the quasi-freudian terms of intrapersonality conflicts among id, ego and super ego; however, it is recognized that while neutral, permissive psychoanalytic treatment may help the overinhibited child, kindly but firm disciplinary measures are necessary for the unsocialized delinquent, and broadened social contacts are needed by the budding little gangster. Despite the fact that the language of this monograph is so generalized that explicit conclusions are not clearly stated even in the final summary, the publication will prove of interest to sociologists, psychiatrists and other workers in the field of mental hygiene.

Cardiovascular Disease in General Practice. By Terence East, M.A., D.M., F.R.C.P., Physician-in-Charge of Cardiological Department, King's College Hospital, London. Second edition. Cloth. Price, 12s. 6d. Pp. 198, with 40 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London W C. 1, 1946.

Most American physicians are advocates of brevity in medical writing, provided comprehensiveness is not sacrificed to brevity. Dr. East has attempted this almost impossible task and in less than 200 pages of text has undertaken to cover the field of cardiovascular diseases. The author presents his book to the general practitioner of medicine with the statement that it is important that he understand diseases of the heart. While no one would dispute this statement, it is obviously impossible to cover adequately a field as extensive as the one under discussion in such an abbreviated manner.

The general practitioner, as far as medical authors are concerned, has more or less been the "forgotten man." It is therefore important that his refresher education be based on solid principles and not on the superficial handling of important phases of disease. Modern medical teaching, both undergraduate and graduate, is committed to the proper teaching of pathologic physiology. This is particularly true in dealing with diseases of the heart and circulation, where the whole mode of treatment and management depends on a clear understanding and correct interpretation of the abnormal physiologic disturbances which prevail in a given patient. Owing to the abridgment of Dr. East's textbook, this important phase of the subject has not received proper consideration and emphasis. The present day status of medicine no longer permits treatment to be based on subjective phenomena alone.

Many subjects in the book are treated with such brevity as to be unenlightening and certainly cannot offer constructive assistance to the physician whose knowledge of the subject is limited. For example, the problem of congenital anomalies of the heart is covered in seven pages. Similar criticisms are applicable regarding other disease entities.

Modern accessory methods of diagnosis are literally ignored. One and a half pages are devoted to electrocardiography and roentgenography. Does this imply that the diagnostic information furnished by these methods of examination should be withheld from the general practitioner of medicine? This is quite contrary to the American philosophy of medical education. No short cut exists for the acquisition of medical knowledge. There is no doubt that the author's experience and knowledge would permit him to produce a truly helpful and comprehensive work which would completely fulfil his intentions.

Maternity Homes for Unmarried Mothers: A Community Service. By Maud Morlock and Hilary Campbell. United States Department of Labor, Children's Bureau, Publication No. 309. Paper. Price, 20 cents. Pp. 94. Supt. of Doc., Government Printing Office, Washington, D. C., 1946.

This publication of the United States Children's Bureau traces historically the efforts that have been made in the United States to provide maternity homes for unmarried mothers, and it reviews the changes that have occurred in attitudes toward this problem. The first institutions that could be considered maternity homes for unmarried mothers were founded in the middle of the nineteenth century under religious auspices or motivations. At the present time there are approximately two hundred such homes in this country. The problem is reflected by the fact that over 80,000 live births out of wedlock are reported each year for the United States. The second part of this pamphlet sets forth the point of view of the Children's Bureau as to the manner in which the maternity home can best meet the needs of these unmarried mothers and their infants, and the suggestions offered are intended primarily for those who operate such homes and for the case work agencies with which they cooperate. The pamphlet covers in detail case work service to the mothers and their babies, through either a case worker attached to the staff of the home or from a social work agency, and also discusses group activities, health and medical services and the organization of the home.

Currents in Biochemical Research. Edited by David E. Green. Thirty-One Essays Charting the Present Course of Biochemical Research and Considering the Intimate Relationship of Biochemistry to Medicine, Agriculture and Social Problems. Cloth. Price $5. Pp. 486, with illustrations. Interscience Publishers, Inc., 215 4th Ave., New York 3, 1946.

Biochemistry, in common with practically all other sciences, has advanced so rapidly in recent years that no individual may hope to become an expert in more than a small corner of this vast field. And since each branch of a science tends to develop its own terminology, the scientist away from his own specialized field becomes a layman distinguishable from other laymen only by his understanding of general scientific principles and methods. For this reason, books which attempt to give a comprehensive view of a science by stripping away the barriers of technical nomenclature are valuable not only to workers in that particular science but also to students of all science and especially to students of related sciences. Thus, this book, edited by Green, will be found interesting and useful not only by biochemists but also by physicians and medical scientists interested in obtaining a broad view of the entire field of biochemistry. For here in accurate but not too technical terms about thirty distinguished research workers in biochemistry have described the important developments in their own specialized fields and indicated the trends of future developments in those fields. There are thirty-one chapters dealing with such topics as genes, viruses, vitamins, hormones, enzymes, photosynthesis, nutrition, metabolism and immunochemistry. The result is a readable and stimulating volume from which the student will gain a broader insight not only into biochemistry itself but also into the intimate relationships between biochemistry and agriculture, biology and medicine. Although each chapter contains references for more specialized reading, the value of the book as a reference work would have been enhanced by the inclusion of an index.

Tuberculosis in the West Indies: Report on Sociological and Clinical Survey [1943, 1944]. By W. Santon Gilmour, M.B., Cloth. Pp. 221, with illustrations. National Association for the Prevention of Tuberculosis, Tavistock House N., Tavistock Square, London W. C. 1, [n. d.].

This bound report is based on an investigation (1943-1944) of tuberculosis in certain of the West Indian colonies. The project was supported by the British National Association for the Prevention of Tuberculosis, under whose auspices similar investigations had previously been made in Cyprus and Burma.

Twelve photographs are included, which portray housing and other conditions on these islands. In Trinidad and Tobago tuberculin surveys revealed that 44.3 per cent and 22.2 per cent of the urban and rural school children respectively reacted to tuberculin. In some towns as high as 100 per cent of adults were infected, with a lower percentage in the rural communities. Among children x-ray inspection of the chest revealed evidence of calcification in 20 per cent. However, the author does not state whether an attempt was made to determine how much of this was due to tuberculosis. The tuberculosis mortality rate decreased from 275 per hundred thousand in 1896 to 100 in 1943. Not enough beds are available to isolate contagious cases. Therefore ambulatory artificial pneumothorax is recommended whenever it is indicated.

In a remote rural area in the Barbados 50 per cent of adults reacted to tuberculin, in an area nearer the town 80 per cent, and in the urban area 100 per cent. The mortality rate was 127 in the urban and 31 per hundred thousand in the rural area.

In Granada, one of the Windward Islands, about 20 per cent of the urban and 12 per cent of the rural children reacted to tuberculin. The mortality rate was 79 per hundred thousand. On St. Lucia over 60 per cent of the urban and nearly 45 per cent of the rural children reacted to tuberculin. The mortality rate was 96 per hundred thousand. On the Leeward Islands the percentage of children reacting to tuberculin ranged from about 7 to 33. The highest mortality rate, over 250 per hundred thousand, in the West Indian colonies was found in the Bahamas. This is 500 per cent higher than in the United States and 400 per cent higher than in the British Isles.

Throughout the West Indian colonies the author found a low incidence of extrathoracic clinical tuberculosis. Generally speaking, tuberculosis has not been a serious problem among the cattle. However, in Antigua of the Leeward Islands the tuberculosis rate is high among the oxen but low among the dairy cows. The author has strongly recommended such procedures as testing young children with tuberculin in seeking the sources of their infections. He recommends the greater use of all diagnostic facilities, isolation of contagious cases, ambulatory artificial pneumothorax and other forms of collapse therapy.

This sociological and clinical survey provides a fine view of the problem in the West Indian colonies, and the recommendations which Dr. Gilmoure has made are excellent for its solution. The British National Association for the Prevention of Tuberculosis has contributed a splendid service by making this monograph possible and in planning for further similar projects.

The Technical Minutiæ of Extended Myomectomy and Ovarian Cystectomy. By Victor Bonney, M.S., M.D., B.Sc., Consulting Gynæcological and Obstetric Surgeon to the Middlesex Hospital, London. Cloth. Price $6.50. Pp. 282, with 242 original drawings by the author. Paul B. Hoeber, Inc., 49 E. 33d St., New York 16; 90 Great Russell St., London, W. C. 1, 1946

This book is by one of the leading British gynecologists and is his justification for the operation of myomectomy. He reports some 632 myomectomies with a 1.1 per cent maternal mortality. He speaks of removing as many as 225 myomas from one uterus and of removing as much as 21 pounds of tumor from 1 patient and still leaving the uterus in each instance. Slightly more than half of the patients were followed up; in 2.3 per cent fibroids recurred; in approximately 2 per cent the menorrhagia recurred. Of about half of the patients followed up pregnancy occurred in 38 per cent, or a total of 52 patients became pregnant. In America multiple myomectomy in general was given up several decades ago because of the initial high mortality and especially the late mortality due to intestinal obstruction. Bonney describes 301 cases in which he was able to peel off enough ovarian tissue from large ovarian tumors, thus preventing castration. Ninety patients had a follow-up, and of 48 patients in whom conception was possible 16 became pregnant. It is not stated how many of the myomectomies and cystectomies were definitely indicated in women who were anxious to have children. The drawings with their extensive legends make up the greater part of the book. It belongs only in the libraries of medical schools.

The Etiology of Deaf-Mutism with Special Reference to Heredity. By Harald Lindenov. Translated from Danish by Axel Andersen. Paper. Pp. 268, with illustrations. Einar Munksgaard, Norregade 6, København, K, 1945

This monograph by Lindenov represents a study of 480 deaf-mutes among thirty-two families living on the Danish islands of Seeland, Lolland and Falster. On the basis of his study the author concludes that sporadic deaf-mutism has a strong hereditary determination and that the inheritance tends to follow a simple autosomal recessive mode. This is in general agreement with the conclusions of previous investigators. The author also concludes that so-called acquired deaf-mutism may in many instances occur only when a hereditary predisposition exists. His evidence for this interpretation, though very suggestive, is not conclusive. To a geneticist the analysis of the available data does not seem complete. However, all in all, the study is an excellent one. It represents the type of genetic investigation that is needed with respect to all those human characteristics which are believed to have some hereditary basis but for which few data are available. It may be appropriate in this connection to point out that studies of the type exemplified by Dr. Lindenov's monograph are few and far between in the United States. Opportunities, however, abound everywhere.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

TREATMENT OF ACUTE CORONARY OCCLUSION

To the Editor:—What is the present treatment of acute coronary artery occlusion? Has the use of papaverine been discarded? Is Dicumarol being used in coronary thrombosis? Is aminophylline of much value?

M.D., California.

Answer.—There is as yet no newly introduced therapy for acute coronary occlusion that has made much difference to the course of the disease despite the occasional enthusiasm for one new measure or another. The therapy that is most favorably regarded by the majority of clinical observers consists in the treatment of the acute attack and in the following convalescent care.

Pain itself, which is almost invariably the important initial symptom of acute coronary occlusion, is best controlled by morphine sulfate, which may be given intravenously for more rapid action. The necessary dosage of morphine varies from ⅙ to ½ grain (0.01 to 0.03 Gm.) or more (in divided doses). It is unwise to give more morphine than is absolutely necessary, because of the disagreeable nausea and vomiting that may be induced thereby and because of the depression of respiration and gastrointestinal function. The administration of atropine may lessen somewhat the vagal overstimulation by the morphine. Aminophylline, papaverine and oxygen have sometimes seemed helpful, particularly oxygen if it is readily available, but usually these measures are not essential. Nursing care is of prime importance, and if there is a state of shock, treatment should be directed against that; the experiences of some have indicated the possible, sometimes lifesaving, value of plasma itself in extreme cases. Most patients, however, do not have a high degree of shock.

The convalescent care includes rest in bed for a minimum of three weeks, a period which will suffice in a large number of cases but may need to be lengthened if there are complications. It is a common practice for rest in bed to be prescribed for three to four weeks and then for a month to be devoted to the return to a normal quiet life, the first week sitting in a chair more each day, the second week walking around on a level more each day, the third week going up and down stairs once a day and the fourth week getting out and around. It is often helpful and wise to arrange for a third month to consolidate the convalescence and to get the person back into good condition physically and mentally.

The use of Dicumarol or heparin, either to prevent coronary thrombosis or its spread or to treat the condition itself, hoping thereby to reduce the amount of intracardiac thrombosis, is still in the experimental stage. One of the important complications of coronary thrombosis is pulmonary embolism from venous thrombosis of the legs, and therefore it is well to keep the leg muscles, especially the calf muscles and feet, quietly active even during the first weeks in bed. This can be done without harm in the absence of important complications.

Other therapy during convalescence such as the use of digitalis and aminophylline depends on the need; in other words, symptomatic therapy should be the rule. A measure of possible importance and value, though difficult to prove, consists in the regular administration of quinidine sulfate 0.2 Gm. (or 3 grain) tablets four to six times a day. This may avert ventricular fibrillation during the first two weeks of the illness.

LOW BLOOD UREA NITROGEN

To the Editor:—A patient has an abnormally low blood urea nitrogen as an incidental finding. Most of the determinations are about 4 mg. per hundred cubic centimeters. The usual causes of a low blood urea nitrogen, such as severe liver disease, low protein intake or excessive fluid intake, have been ruled out as well as the possibility of a laboratory error. Please give references to similar cases in the literature and the possible mechanisms involved in such an abnormal lowering of the blood urea nitrogen.

M.D., Illinois.

Answer.—Either the normal limits of blood urea nitrogen or the technical error of its determination or both are subject to wider variations than is generally appreciated. The significance of very low values for blood urea nitrogen has been discussed by Bowman, R. O.; Crowell, F. F., and Oslon, L. F.: *J. Lab. & Clin. Med.* 30:706 (Aug.) 1945.

POSSIBLE PARINAUD'S CONJUNCTIVITIS

To the Editor:—A woman aged 35, who is a grocery clerk, gives the following history: For two weeks she had noted soreness at the outer angle of the left upper eyelid. A few days later she developed a preauricular adenitis which gradually became more swollen, moderately painful and extended beneath the angle of the left mandible. She had been using sulfadiazine ointment in the eye. The eyelids stuck together when she arose. *There had been no pain in the eye and no disturbance of vision.* The pupil of the right eye had been somewhat larger than that of the left for a long time and the patient did not think that this finding was related to the present condition. Physical examination revealed a temperature of 99.4 F. and pulse rate of 88. There was a large preauricular adenitis, firm, moderately tender, and nonsuppurative with some reddening of the skin. The left upper eyelid was mildly edematous. There was a minimal bulbar conjunctival reaction consisting of some engorgement of the vessels in the outer angle of the eye. Both upper and lower palpebral conjunctivas were acutely inflamed. There was no tearing and no discharge. Over the upper palpebral conjunctiva there was a thin, whitish exudative film which was mildly tenacious but could be removed without difficulty and without bleeding. At the outer angle of the left upper palpebral conjunctiva, about 1/8 inch from the lid margin, there was a papillary mass about 3/16 inch in diameter and elevated about 1/16 inch. The sharp, sloping under edges of this mass gave it the appearance of a small toadstool. It was not pedunculated, tender or ulcerated. The left pupil was smaller than the right, but both reacted well to light and in accommodation. Ocular tension was normal. The cornea, iris, lens, media, fundus and disk were normal. Smears made from the exudate and from conjunctival scrapings did not show inclusion bodies, bacteria or eosinophils, but many pus cells were present. The right eye was normal except for a questionable minimal exophthalmos. Treatment consisted in bed rest, warm moist compresses, 0.25 per cent zinc sulfate and codeine. The condition was unchanged after two days' treatment. Penicillin ophthalmic ointment was then prescribed, followed in one day by a slight decrease of the bulbar conjunctival reaction. During the next forty-eight hours the patient was given 360,000 units of penicillin intramuscularly in a dosage of 20,000 units every three hours. Twelve hours after the penicillin was started the pain disappeared and in four days the bulbar conjunctival reaction had completely subsided. The adenitis decreased progressively until it had practically disappeared after two weeks. The papillary mass remained about the same size and was treated with 1 per cent silver nitrate followed by irrigation with boric acid. Please discuss the nature of this illness and of the small mass on the upper lid. There was no history of possible tularemia or syphilis. What is the cause of the inequality of pupils?

M.D., Kentucky.

Answer.—It is difficult to make a diagnosis of the lesion described in the query. It is possible that a biopsy, culture and animal inoculation of the papillary conjunctival mass described would have given considerable information regarding the cause of this condition. It might not be too late at this time to excise the small mass, have part of it preserved for microscopic examination and the other part used for animal experiments, bacterial smears and cultures. Leptothricosis is a strong possibility. The organism is difficult to demonstrate, and every effort should be made to do this. The case described resembles Parinaud's conjunctivitis. Tularemia should be excluded by agglutination test of the blood in spite of the splendid response to penicillin, which would tend to rule out tularemia.

A unilateral dilated pupil may indicate some irritation of the cervical sympathetic, provided one is sure that there has been no local trauma to produce a paralysis of the sphincter. Irritation of the cervical sympathetic can be due to a lung apical lesion, pressure from the thyroid gland, enlargement of the mediastinal glands, cervical rib or other lesions in the area of the cervical sympathetic nerve.

PREGNANCY AND BRUCELLOSIS

To the Editor:—A woman has chronic undulant fever and is well controlled by brucellin therapy. She is now over six months pregnant, is in good physical condition and is pursuing a normal course. Can she breast nurse the baby without any danger of transmitting undulant fever through her milk to the newborn? What are the chances of premature birth in women with chronic undulant fever? In a previous pregnancy, at which time the undulant fever was unrecognized, she was in poor physical condition and gave birth when the fetus was 7 months old.

M.D., New Mexico.

Answer.—A good publication covering these questions is the paper on Undulant Fever in Children, by O. E. Hagebusch and C. F. Frei (*Am. J. Clin. Path.* **11**:497 [June] 1941). There is not enough experience to answer the first question satisfactorily. Insufficient additional unpublished experience indicates that the better the mother's disease is controlled during pregnancy and during lactation the safer it is for the babies to nurse, but it should be noted that the paper cited presents exceptions.

Morbidity data are inadequate to permit even an estimate of the frequency of abortions or premature deliveries caused by brucellosis. The paper cited documents a number of examples. It is known that for a small number of women who had previously experienced abortions or premature deliveries caused by brucellosis, favorable responses to vaccine therapy were accompanied with normal gestation periods and normal postpartum courses.

RECURRENT PHARYNGITIS

To the Editor:—A married woman aged 27 has had recurrent episodes of "sore throat" for many years. A tonsillectomy was performed at 6 years of age but the adenoids were not removed. At 12 years of age some lymphoid patches were removed from the pharynx. Attacks of pharyngitis occur from two to four times a month, regardless of season, usually without any known precipitating factor. Some attacks are accompanied with considerable thick postnasal secretion. Mouth breathing at night is usual. She has an angiospastic tendency: the hands and feet are usually cold during the winter months, and a few years ago on several occasions the fingers became bluish red while the patient was working indoors. Her general physical condition is good. Her height is 5 feet 8 inches (173 cm.), her weight 140 pounds (63.5 Kg.). The oropharynx presents patches of hypertrophied lymphoid tissue alternating with areas of pale mucosa where dilated vessels are seen during attacks. The nasopharyngeal vault contains reddish, scarred adenoid tissue. The basal metabolic rate was minus 15 and remained at this level on thyroid 1 grain (0.06 Gm.) per day. For four months she has been taking 25,000 units of vitamin A daily in addition to a normal diet. Recently she has received three x-ray treatments one month apart directed towards the nasopharynx and the oropharynx. The last treatment was given two months ago; no particular relief has been noted, for she recently had three attacks within a fortnight. The throat during one severe attack this winter yielded a pure culture of hemolytic streptococcus. Most of the episodes are controlled in a few days with sulfadiazine in small doses, but the repeated use of this drug seems inadvisable. Please discuss treatment. M.D., New York.

Answer.—It is not easy to make a diagnosis in the case described in the query, but it is hard to believe that the frequently recurring attacks of pharyngitis are independent of a local or general cause. Because the general physical condition is stated to be good, the most likely local cause to be sought would be a suppurative sinusitis. It is not likely that the sinuses involved would be the obvious ones, such as the frontal or maxillary sinuses. It is more probable that a suppurative condition, if present, would be in the posterior ethmoidal or the sphenoidal sinuses.

The first step in diagnosis would be an x-ray examination of all the sinuses. Iodized oil studies could be done at the same time. Probing and washing of all the suspect sinuses would be next in order. Discovery of a sinus suppuration, let us say in a sphenoidal sinus, could account for many if not all of the symptoms described. Treatment thereafter would be dictated by response to the usual therapeutic measures.

By a careful history, examination of nasal smears and skin testing an attempt should be made to determine the presence or absence of an allergic factor. Combinations of suppurative and allergic states are frequently stubborn, at times obscure, and capable of giving a clinical picture as described in the query.

VASECTOMY

To the Editor:—Two patients with moderate enlargement of the prostate and few symptoms of urinary or other disturbance have been told by their physicians that vasectomy should be performed to prevent enlargement and cancer of the prostate. What are the effects of vasectomy?

F. A. Mills, M.D., Rawlins, Wyo.

Answer.—Vasectomy will have no effect whatever on an enlarged prostate gland. It will not prevent cancer of the prostate. It is not indicated in the treatment of any disease of the prostate. It is done routinely in some clinics previous to operations for prostatic hypertrophy to prevent epididymitis.

AFTER-EFFECTS OF PROLONGED PENICILLIN ADMINISTRATION

To the Editor:—A patient received a large amount of penicillin for a long time. Have any renal or intestinal after-effects been reported from the prolonged administration of penicillin?

William D. Baun, M.D., Philadelphia.

Answer.—Aside from the patients who become sensitized to penicillin there is no evidence that there are any other after-effects. There is no literature that can be found indicating that there are renal or intestinal after-effects.

TOXICITY OF DETERGENTS

To the Editor:—What detergents are harmless if swallowed?

Reuben E. Stone, M.D., Washington, D. C.

Answer.—None of the newer chemical detergents are known to be perfectly safe to take by mouth. General information on cutaneous detergents may be found in the article by C. Guy Lane and Irvin H. Blank in The Journal, March 7, 1942, page 804.

SPECIFICITY OF WEIL-FELIX REACTION

To the Editor:—Please discuss the agglutination of proteins OX 19 (Felix-Weil reaction) in such diseases as pneumonia and infectious hepatitis. Positive agglutinations have been found in cases in which a diagnosis of virus pneumonia or hepatitis has been subsequently established.

Arthur R. Abel, Orange, N. J.

Answer.—The agglutination of the proteus OX strains (Weil-Felix reaction) is primarily of value in the laboratory diagnosis of certain rickettsial diseases. Since these proteus strains have nothing whatever to do with the etiology of the rickettsial diseases, the Weil-Felix reaction must be considered nonspecific. It is not surprising, therefore, that low titered reactions have been reported from a wide variety of clinical conditions, including cancer, malaria and pregnancy. Cross reactions with relatively high titers have been observed in typhoid, brucellosis, tularemia and Weil's disease, to mention a few. The sensitivity and specificity of the test vary considerably from laboratory to laboratory. Reliance on the Weil-Felix reaction as a diagnostic aid in rickettsial disease should rest primarily on the rise and fall in titer rather than on a single test. More specific tests for the rickettsial diseases, such as complement fixation and rickettsial agglutination, are gradually superseding the Weil-Felix test in many laboratories.

TENDON SUTURES IN FINGER AMPUTATIONS

To the Editor:—In a recent article in *Surgical Clinics of North America* Mock advocates in amputation of fingers the suture of flexor and extensor tendons to one another across the stump. In a recent article in the *Journal of Bone and Joint Surgery* this is not advocated in finger amputations. M.D., New York.

Answer.—Bunnell long ago emphasized the importance of not suturing flexor and extensor tendons to one another over the stump of an amputated finger, but on the contrary dividing them as far proximal as possible and permitting them to retract.

Both flexor and extensor tendons of the four fingers work more or less synchronously. They could be compared to a four horse team without horses harnessed abreast of one another. If one horse plants his feet firmly and refuses to move the team doesn't get very far.

Fixation of the ends of the tendons of an amputated finger can be so complete that secondary operation to free them may be necessary to permit free movement of the adjacent fingers.

SIGNIFICANCE OF BREAST STRIAE

To the Editor:—A Negro woman aged 30, unmarried, has white striae about both nipples, extending nearly to the bases of the breasts, and two lemon sized masses in the right and left iliac fossae apparently involving the ovaries. Are the striae positive signs of previous pregnancy or can they be due to uterine fibroids or disease of the uterine adnexa? M.D., Florida.

Answer.—Striae of the breast radiating from the areolas are not an absolute indication of pregnancy. They may develop during adolescence, particularly in the obese girl with large breasts. Striae over the thighs are likewise seen during this developmental period when the immature girl develops the mature figure. Striae of the lower part of the abdomen are less often associated with puberty and adolescence and are more often associated with or a residual finding of gestation. However, here too its presence must not be accepted as an absolute sign of a pregnancy.

Abdominal striae are thought to be due to the hypertrophic changes in the abdominal wall associated with pregnancy rather than to the distention by the growing uterus. The striae of the breasts and hips may have a similar etiology.

CORNEAL TATTOOING

To the Editor:—In Queries and Minor Notes (Nov. 2, 1946, p. 546) is an answer to the question "Is there a better method of corneal tattooing than using 2 per cent platinum chloride followed by 2 per cent aqueous hydrazine hydrate?" I should like to point out that the pupillary area of the cornea is not the only zone where tattooing is indicated. The cosmetic effect of tattooing may be indicated on any part of the cornea. Platinum chloride and hydrazine hydrate solutions, therefore, are not the only ones to be used. Gold chloride followed by epinephrine gives a brown iris effect for the extrapupillary area. Then too, platinum chloride alone will not always give the desired effect, so occasionally the combination of platinum and gold over the pupillary area will result in a blacker pupil. It might also be mentioned that it is feasible to tattoo both black and brown in juxtaposition. Another point of importance is the fact that it is unnecessary to use a trephine to give the appearance of a round pupil, for it is surprising how well an irregularly outlined area looks. Arthur Alexander Knapp, New York.

TUBERCULOSIS CASE FINDING

A Comparison of the Effectiveness of Various Roentgenographic and Photofluorographic Methods

CARL C. BIRKELO, M.D., Detroit
W. EDWARD CHAMBERLAIN, M.D., Philadelphia
PAUL S. PHELPS, M.D., Hartford, Conn.
PERCY E. SCHOOLS, M.D., Richmond, Va.
DAVID ZACKS, M.D., Boston
and
JACOB YERUSHALMY, Ph.D., Washington, D. C.

Within a relatively short time photofluorography has been transformed from a crude experiment to an efficient diagnostic aid. It may be estimated that within the last six years some 20 million Americans have had x-ray examinations of the chest. The vast majority of these would not have had this service if they had had to depend on the conventional 14 by 17 inch celluloid film. The outlook for the future is that mass radiography will further expand and that a majority of the adult population will receive this service.

The radiographic technics and sizes most commonly used are 35 mm. photofluorography, 4 by 10 inch stereophotofluorography, roentgenography on 14 by 17 inch paper and film negatives and, in recent months, 70 mm. photofluorography. Individual preferences for one or the other of these technics are based, as far as can be determined, on considerations of economy, ease of operation, individual likes and dislikes and availability of the different machines. However, the most important, indeed the crucial, determining factor must, in the final analysis, be their relative diagnostic efficiency, i. e. the ability of the different methods to detect pulmonary lesions. Up to now no comprehensive study has been made in this country in which all the technics were subjected to a rigorous test.

The need for such a comprehensive evaluation of the different roentgenographic and photofluorographic methods was realized early in 1944 by the administrator of veterans' affairs. The Veterans Administration was faced with the problem of keeping on file and evaluating at least two films for each veteran: one taken at the time of induction and one taken at the time of discharge, as well as some others which may have been taken during the period of service in the armed forces. Some of these were 35 mm., 4 by 5 inch or 4 by 10 inch photofluorograms; others were the conventional 14 by 17 inch celluloid films. General Hines, then administrator of veterans' affairs, therefore appointed a Board of Roentgenology to investigate this problem. The mandate given this board was to investigate the relative diagnostic efficiency of the various technics, neglecting all other considerations, such as cost and ease of operation.

The Board of Roentgenology appointed by the administrator of veterans' affairs consisted of Dr. C. C. Birkelo of Detroit, Dr. W. Edward Chamberlain of Philadelphia, Dr. Paul Phelps of Hartford, Conn., Dr. Percy Schools of Richmond, Va., and Dr. David Zacks of Boston. The members elected Dr. W. Edward Chamberlain chairman of the board. At the request of the administrator the U. S. Public Health Service made available the services of Dr. Jacob Yerushalmy as statistician to assist in the direction and analysis of this study.

MATERIAL AND METHOD OF INTERPRETATION

In selecting the material on which to base this study the board was desirous of simulating as nearly as possible the conditions of mass survey work for which these technics are ordinarily utilized. Accordingly, the entire population of two Veterans Administration institutions, one located in Bronx, New York, the other in Dayton, Ohio, were surveyed. The populations in these institutions were of three different types: (1) employees, (2) ambulatory patients of a general hospital and (3) residents for domiciliary care. The last group consisted, in the main, of relatively old veterans of World War I.

A 35 mm. photofluorogram, a 4 by 10 inch stereophotofluorogram, a roentgenogram on a 14 by 17 inch paper negative and a conventional 14 by 17 inch celluloid film[1] were taken within a few minutes of one another on each person participating in the study. The companies providing the machines[2] made special efforts to produce films of the best possible quality.

The material for the study provided by the survey consisted of a set of 14 by 17 inch celluloid films and similar sets of 35 mm. and 4 by 10 inch photofluorograms and 14 by 17 inch paper negatives, all on the same individuals taken at the same visit. These four sets of films were interpreted independently by the five

This paper has been abbreviated on account of limitations of space. The complete paper can be found in the authors' reprints, which will be available on request.

Mrs. Sarah E. Yelton of the U. S. Public Health Service and Mrs. Ruth Levey of the Veterans Administration rendered assistance in assembling and analyzing the material used in this paper.

Published with the permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or the conclusions reached by the authors.

[1] At the time the survey was conducted, the 70 mm. technic had not yet been developed.

[2] The 4 by 10 inch stereophotofluorograms were taken and processed by the General Electric Company, the 14 by 17 inch paper negatives were taken and processed by Powers X-Ray Products, Inc., the U. S. Public Health Service made available and processed the 35 mm. films, using a Westinghouse machine, and the 14 by 17 inch celluloid films were taken with the Veterans Administration Picker machine. Eastman Kodak provided the technicians for the operation of the Picker machine and developed the 14 by 17 inch celluloid films.

members forming the Board of Roentgenology. The procedures used were as follows:

Prior to reviewing any of the films the board convened, reached agreements on nomenclature and developed a code for classifying the films into distinct categories in as uniform a way as possible. Members of the board also reviewed samples of films made with the various technics (not included in the study), classifying them independently and in conference, in an attempt to arrive as nearly as possible at uniformity in nomenclature. This provided an actual test of the suitability of the code.[3]

Each reader received only one group of films at a time. In no case did a reader review the 14 by 17 inch celluloid films before he had completed his interpretations on all the other technics. No reader received a group of films for any technic while he had the corresponding group for another technic. After all the interpretations of the four technics were received, and after a lapse of at least two months, the 14 by 17 inch celluloid films were again sent to each reader for a second independent interpretation

Because the studies of the Dayton films are as yet incomplete, the present report is based on the analysis of the Bronx series only. The 1,256 films taken there form the basis for this report.

TABLE 1.—*Readers Calling 14 by 17 Inch Films Positive*

Number of Readers Calling Film Positive for Tuberculosis	Number of Films
1	47

3	17
4	17
5	27

ANALYSIS

The object of the analysis is to obtain a measure of the efficiency of the different technics in selecting the individuals with chest disease from among the study group. Specifically, the following two measures need to be obtained for each technic.

1. The percentage of persons with chest disease whose films were read as negative by the technic (underreading or misses)

2 The percentage of films called positive by the technic on persons having no chest disease (overreading or false positives)

Obviously, care must be taken that these indexes should measure the limitations of the technic and not the subjective errors of the readers.

In order to be able to obtain the two percentages, it becomes necessary to devise means for identifying the persons in the study group who have roentgenologic evidence of chest disease.

This simple question is the most crucial and the most difficult to answer. As an illustration of the difficulties involved it may be well to list the different kinds of answers that may be obtained to the question of how many persons in the study are positive for tuberculosis.[4]

On the basis of the 14 by 17 inch celluloid film interpretations there were 131 cases called positive by one or more readers. For the different readers the number of "positives" varied from 56 to 100. In other words, there was one reader who selected only 56 positives, one with 100 positives and 3 with an intermediate number of positives.

The number of cases called positive by a single reader on one or more technics varied from 74 to 170. The number of cases called positive by one or more readers on one or more technics was 262.

Other and probably more desirable methods of defining positive cases are those which reflect "group opinion." For example, the 14 by 17 inch celluloid film interpretations may be tabulated according to the number of readers calling each film positive. This yields the tabulation presented as table 1. This table not only affords a method of defining positive cases in different ways, but also yields a measure of reliability which may be attributed to each definition In other words, the probability that the 27 films which all five readers called positive represent cases of tuberculosis is enormously greater than that of the 47 cases represented by films which were called positive by only one of the five readers. A large proportion of the latter, no doubt, represent overreading on the part of one or the other of the readers.

As a practical point of departure a case of tuberculosis may be defined as one which a majority of the readers (three or more) called positive on the 14 by 17 inch celluloid. Under this definition there were 61 positive cases.

This discourse on the wide variability of the possible number of positive cases, confusing as it is, is presented because it is an essential starting point for the analysis. The purpose of mass x-ray surveys is to identify the individuals in the group requiring further study. If the number of such individuals cannot be determined, it would obviously be impossible to measure the efficiency of the various technics. Moreover, the purpose of the study is to evaluate the deficiencies of the different technics which are due to the limitations of the technic itself and not to extraneous factors. It is obvious from the procession of figures given that even when limited to one technic, the 14 by 17 inch celluloid, tremendous variation exists among the different readers Consequently, variations among the different technics, as measured by underreading and overreading, represent a composite picture due partly to the technic and partly to subjective or human errors involved in film interpretation It therefore becomes important in the analysis to attempt to develop methods which would eliminate, or at least greatly reduce, the subjective errors of interpretation and retain only that part of the variation which is inherent in the technic.

As an initial step it may be well to attempt to obtain measures for the subjective errors. These subjective errors are of two main types:

1 Interindividual variation, or the failure of an individual reader to be consistent with other readers in interpreting the same set of films

2 Intraindividual variation, or the failure of a reader to be consistent with himself in two independent interpretations of the same set of films

Interindividual Variation.—A measure of the magnitude of the interindividual variation may be obtained by comparing the interpretations of the five readers on the 14 by 17 inch celluloid films. The result of this analysis is shown in table 2. In this table the interpretations of each reader are compared with those of each of the other readers in two ways. In the first part of the table the requirements of consistency are more strict than in the other, in that it is required that both readers agree on the diagnosis of tuberculosis. In the second part of the table two readings are considered to be in agreement also when one of them is that of nontuberculous disease or even if it is read "essentially negative" with a notation of "pulmonary scars."

---

[3] A detailed description of the code will be given in a future publication. Briefly, the code provided for the classification of a film in broad pathologic categories and in specific diagnostic classifications In addition whenever a reader observed evidence of tuberculosis, he was required to indicate on a rib cage diagram the location and character of the observed lesions For such cases he was also required to express his impression regarding activity in terms of three classifications "probably active," "questionably active" and "probably inactive"

[4] The analysis in this report will be limited to tuberculous lesions The question of nontuberculous lesions will be dealt with in a subsequent paper

The meaning of the table can probably be made clearer by following across any of the rows, such as the one headed *N*. There were 59 films called positive for tuberculosis by reader *N*. The table shows (underscored figures) that reader *M* called 31 per cent of these "negative for tuberculosis," reader *O* 29 per cent, reader *P* 37 per cent and reader *Q* 14 per cent. The second part of the table shows that under the more liberal interpretation there were very large reductions in the percentage disagreement. For example, the disagreement with reader *M* is reduced from 31 per cent to 5 per cent, with reader *O* from 29 to 10, with reader *P* from 37 to 19, and with reader *Q* from 14 to 7 per cent.

It is striking that experienced radiologists and chest specialists find such difficulty in being consistent with one another in classifying films in broad categories of evidence of tuberculosis. It is even more surprising to find in some cases that 20 per cent of the films which were called positive for tuberculosis by one reader were called negative by another.

Intraindividual Variation.—Some of these differences are, no doubt, due to the varied background and experience of the five readers. However, this by no means accounts for the entire variation because considerable differences are noted also when the same individual reads the same set of films a second time. A measure of this intraindividual variation may be obtained from table 3, which compares for each of the five readers his two independent interpretations of the 14 by 17 inch celluloid films.[5]

The meaning of table 3 may probably be best explained by following one of the rows. For example, reader *N* read 59 films as positive for tuberculosis on his first reading. Of these he called 7 per cent of the cases negative for tuberculosis on the second reading, and in 3 per cent of the films the second reading was that of straight negative. (See underscored percentages in table 3.) On the other hand, the same reader called 78 cases positive for tuberculosis on the second reading. In 29 per cent of these cases the first reading was negative for tuberculosis and 22 per cent of these cases were called straight negative on the first reading.

A review of table 3 indicates that there are considerable subjective errors in the two independent interpretations of each reader. This variation is not due to any difference in the method of reading between the first and the second time because there was no consistency in the direction of the error among all readers. For example, while readers *M*, *N* and *O* read more positives on the second reading than on the first reading, readers *P* and *Q* had more positives on the first than on the second reading. The major part of the variation, therefore, is due primarily to the inability of an individual reader to be consistent with himself in two independent interpretations of the same set of films.

A COMPARISON FOR EACH READER BETWEEN THE INTERPRETATIONS OF THE 14 BY 17 INCH CELLULOID FILMS AND THOSE OF EACH OF THE OTHER TECHNICS

In nearly all comparative studies of this kind the interpretations of a reader on the study technic are compared with his readings on the standard 14 by 17 inch celluloid films. It may therefore be well to determine from the present study what conclusions can be reached from such a comparison.

TABLE 2.—*Interindividual Variation*

(14 by 17 Inch Celluloid Films Only)

To show how many of the films which were called positive for tuberculosis by each of the five readers were called (*a*) "negative for tuberculosis" and (*b*) "essentially negative" by each of the other readers. ("Essentially negative" means negative for nontuberculous as well as tuberculous disease)

Of Films Called Positive for Tuberculosis by Reader	Number of Films	(a) Percentage Called Negative for Tuberculosis by Reader					(b) Percentage Called Essentially Negative by Reader				
		M	N	O	P	Q	M	N	O	P	Q
M	62	.	34	31	45	19	..	13	11	24	13
N	59	31	..	29	37	14	5	.	10	19	7

P	56	39	34	29	..	11	7	14	11	..	9
Q	100	50	49	42	50	..	14	20	14	20	..

TABLE 3.—*Intraindividual Variation*

(14 by 17 Inch Celluloid Films Only)

To show how many of the films which were called positive for tuberculosis by each of the five readers on one reading were called (*a*) "negative for tuberculosis" and (*b*) "essentially negative" by the same reader on the other reading.

	Second Reading Compared to First			First Reading Compared to Second		
Reader	Number of Films Called Positive for Tuberculosis on First Reading	Percentage Called Negative for Tuberculosis on Second Reading	Percentage Called Essentially Negative on Second Reading	Number of Films Called Positive for Tuberculosis on Second Reading	Percentage Called Negative for Tuberculosis on First Reading	Percentage Called Essentially Negative on First Reading
M	118	16	11	139	29	27
N	59	7	3	78	29	22
O	83	18	12	88	23	13
P	96	41	31	69	17	14
Q	100	22	14	88	6	3

Table 4 presents for each of the five readers the percentage of films called positive for tuberculosis on the standard which he called (*a*) "negative for tuberculosis" and (*b*) "essentially negative"[7] on each of the study technics.[8] Following this table along any of the rows will assist in understanding the meaning of the percentages presented. For example, it will be noted that reader *N* (the underscored row in the table) read fifty-nine 14 by 17 inch celluloid films as positive for tuberculosis. He failed to diagnose tuberculosis in 27 per cent of the corresponding 35 mm. films, in 30 per cent of the 4 by 10 inch films and in 24 per cent of the paper negatives. He failed to note the presence of any lesion (tuberculous or nontuberculous) in 22 per cent of the 35 mm. films, in 29 per cent of the 4 by 10 inch films and in 17 per cent of the 14 by 17 inch paper negatives.

---

[5] Certain adjustments had to be made in constructing this table. Between the first and second reading of the 14 by 17 inch celluloid films the readers decided to change the procedure of recording on films designated "pulmonary scars." At the first reading such a classification could have been given with either a reading of "positive for tuberculosis," "suspicious for tuberculosis" or "essentially negative." A review of these interpretations showed decided inconsistency among the several readers. It was therefore decided that in the second reading "pulmonary scars" were to be given only with the classification of "positive for tuberculosis." Consequently, in comparing the first and second readings, all readings of "pulmonary scars" in the first reading were considered as accompanying the classification of "positive for tuberculosis."

[7] "Essentially negative" means negative for nontuberculous as well as tuberculous disease.

[8] For simplicity, only the problem of underreading is considered here. Overreading will be considered briefly in a later chapter of this report. A more detailed analysis of overreading will be presented at a later date.

From the performance of reader *N* as shown in the table, one would be tempted to conclude, first, that none of the study technics can be considered efficient (the lowest percentage missed is 17) and, second, that if a choice needs to be made among the three study technics, the 14 by 17 paper negatives have an edge over the two miniature technics.

TABLE 4.—*Comparison of Technics*

To show how many of the cases which were called positive for tuberculosis by each reader on the 14 by 17 inch celluloid films were called (*a*)"negative for tuberculosis" and (*b*)"essentially negative" by the same reader on each of the other technics.

Of Films Called Positive for Tuberculosis on the 14 by 17 Inch Celluloid Films by Reader	Number of Cases	(a) Percentage Called Negative for Tuberculosis by the Same Reader on			(b) Percentage Called Essentially Negative by the Same Reader on		
		35 Mm	4 by 10 Inch Stereo	14 by 17 Inch Paper	35 Mm	4 by 10 Inch Stereo	14 by 17 Inch Paper
M	62	29	13	23	13	8	13
N	59	27	30	24	22	29	17
O	70	29	34	41	17	19	23
P	56	4	5	11	4	5	5
Q	100	9	28	13	6	25	9

TABLE 5.—*Cases Missed*

To show how many of the cases which were called positive for tuberculosis by two or more, three or more, four or more or five readers on the 14 by 17 inch celluloid films were called (*a*)"negative for tuberculosis" and (*b*) "essentially negative" by three or more readers on each of the other technics

Number of Readers Calling Case Positive for Tuberculosis on the 14 by 17 Inch Celluloid Film	Number of Cases	(a) Percentage Called Negative for Tuberculosis by Three or More Readers on			(b) Percentage Called Essentially Negative by Three or More Readers on		
		35 Mm	4 by 10 Inch Stereo	14 by 17 Inch Paper	35 Mm	4 by 10 Inch Stereo	14 by 17 Inch Paper
2 or more	84	27	26	29	14	12	10
3 or more ..	61	10	11	10	5	5	5
4 or more	44	5	5	5	2	5	2
5	27	..	4	..	..	4	..

However, neither of these conclusions is justified. For, first, reference to table 3 shows that the same reader *N* missed on his first reading of the 14 by 17 inch celluloid films 22 per cent of those which he called positive for tuberculosis on the second reading of the same 14 by 17 inch celluloid films. In other words, the relatively high percentages shown in table 4 do not necessarily measure the limitations of the different technics, but, to a large extent, the subjective errors in interpretation for reader *N*.

Similarly, it is not possible to conclude that the paper negatives are more reliable than the miniature technics because the same results are not found for all the readers. For example, for reader *M* the score on the 4 by 10 inch is better than on the other two, while for readers *O* and *Q* the 35 mm. stands out better than the others.

It may therefore be concluded that from a simple comparison as shown no valid conclusions may be drawn on the relative diagnostic efficiency of the different photofluorographic technics. Other methods of analysis need to be set up to answer the question under investigation.

It may be added parenthetically that a suggestion that all the study technics are relatively efficient may be obtained from a comparison of tables 3 and 4. This inference is obtained from the fact that nearly every one of the five readers missed almost as many cases on a subsequent rereading of the 14 by 17 inch celluloid films (table 3) as he missed on any of the other technics (table 4).

ANALYSIS OF GROUP PERFORMANCE

In view of the difficulties presented, it becomes necessary to devise a method of analysis which reduces as much as possible the effect of interindividual and intraindividual variations and which, at the same time, accentuates the inherent limitations of the different technics. Such a method, it is believed, may be obtained by basing the analysis on "group opinion." There are a number of valid objections to the "group opinion" definition when such an opinion is obtained in conference and in consultation. In this material, however, a "group opinion" may be obtained which is based on the independent interpretations of the individual readers.

The rationale behind this method of analysis may be formulated somewhat as follows: The classification of an individual, on roentgenologic evidence, as being positive or negative for tuberculosis depends not only on whether or not a shadow exists on his x-ray but also on whether the shadow is such that it can be perceived by an interpreter. In other words, if a shadow can be shown by precision instruments to be present on the x-ray film, but if it cannot be perceived under normal reading practice, such a shadow is for all practical purposes nonexistent

Now if a film has been called positive by only one of five competent readers and negative by the other four, it is idle to speculate whether a lesion is really present and the four have missed it or whether the single positive reading represents overreading. For all practical purposes it may be concluded that, even if a lesion exists, the technic is not capable of identifying it since it escaped detection by four out of five readers.

When a film is called positive by more than one reader, however, greater reliability may be assumed, not only that the case may be positive, but also that the technic in question is capable of detecting the lesion Moreover, the subjective errors are greatly reduced For example, if a reader has a 20 per cent chance of missing a positive film, the chances that the same film will be missed by several readers, each grading independently of the others, are enormously reduced.

With this in mind it becomes possible to measure the relative diagnostic efficiency which is inherent in the different technics. If the 14 by 17 inch celluloid film is considered the standard with which to compare the performance of the study technics, it first becomes necessary to define positive cases by "group opinion" on the 14 by 17 inch celluloid films. The performance of the different technics in selecting the corresponding films for these cases will be a measure of their diagnostic efficiency. The ability of a technic to select these films will again be obtained by "group opinion." In other words, if such a film is called positive on a given technic by only one or even two of the five readers, it may be stated that although the shadow may be present in the study film it is not sufficiently distinct since a majority of the readers missed it.

It should be reemphasized here that it is only because the original readings were independent that the "group opinion" may be used for the purpose. No "conference opinion" can attain the objective quality which is essential to the method.

A practical method of lining up the three study technics would be to determine the percentage of films which were missed on each technic by a majority of the readers (three or more) out of such cases which were called positive by a majority of the readers (three or more) on the 14 by 17 inch celluloid films.

Such a comparison is afforded in table 5 according to several definitions of positive cases, i. e. cases called positive for tuberculosis on the 14 by 17 inch celluloid films by two or more, three or more, four or more or all five readers.

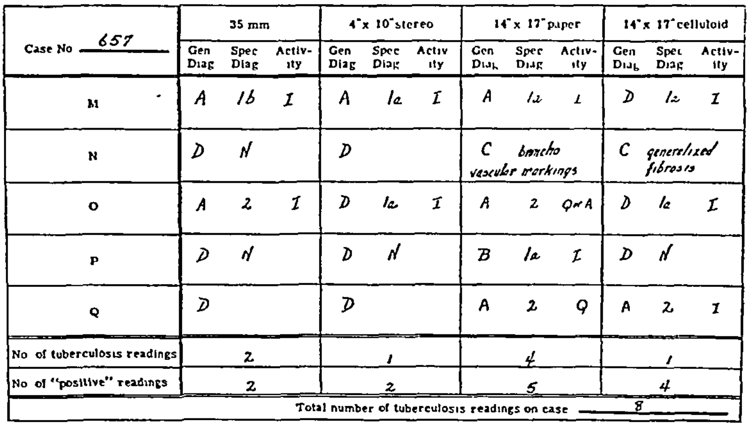
It is striking that, no matter what definition of "positive" is used, the three study technics miss approximately the same percentage of the cases. For example, of the 61 cases called positive for tuberculosis on the 14 by 17 inch celluloid by a majority of the readers (the underscored figures) each technic failed to diagnose tuberculosis for approximately 10 per cent of the cases. In terms of the more liberal interpretation of agreement, the lesion was seen in 95 per cent of the cases on each one of the technics.

It may therefore be concluded that the 35 mm. films, the 4 by 10 inch films, and the 14 by 17 inch paper negatives are equally efficient in selecting positive cases.

OBJECTIVE COMPARISON OF ALL FOUR TECHNICS

In the comparisons made thus far the 14 by 17 inch celluloid film was considered the standard and the performances of the other technics were compared to it. The material available in this study makes possible an objective comparison of the four technics which utilized the evidence provided by all four technics and which is free from any preconceived evaluation of any of the technics. It affords a method of comparison which not only is free from interindividual and intraindividual variation but makes possible also the lining up of the four technics on a number of different levels in terms of different definitions of what constitutes a positive case. A key to this method of analysis is provided by the fact that for each subject in this study there are available four different films. These films were interpreted by five readers, thus providing twenty independent readings or diagnoses. These twenty interpretations can be assembled on one card as is illustrated in the work card. The subjects can therefore be divided into twenty-one groups. One group, the largest (994 persons), consists of those for whom not one of the twenty readings was positive for tuberculosis. The remaining are divided into twenty groups according to the number of positive readings. There were, for example, 101 persons on whom there was only one positive reading out of a possible twenty, thirty-seven with two, fifteen with three positive readings and so on. The final group (in which there were twenty-one) consists of cases in which all twenty readings were positive. The case illustrated in the work card falls in the group with eight readings positive for tuberculosis.

Table 6 provides means for classifying the individuals according to different degrees of "positiveness" for tuberculosis. A case having, for example, only one or two positive readings out of a possible twenty has a smaller probability of being really positive than a case with eight or ten positive readings. In fact it is almost certain that most of the persons in some of the lower groups are not positive at all but represent occasional overreading. As the number of positive readings begins to pile up, the probability of tuberculous disease increases. Certainly the need for further investigation on these cases is increased. This table may therefore be used for the purpose of defining the group which should be selected for further study in a mass x-ray survey. Such definition may vary according to individual practice and preference. The important thing, however, is that, once a definition of "positiveness" is arrived at, it becomes a simple matter to select these "positive" cases and count the number of positive readings given by the five readers on each of the different technics. The technic which is superior to any of the others should furnish a larger number of positive readings on these films than would a technic which was less satisfactory.



Case No 657	35 mm			4"x 10" stereo			14"x 17" paper			14"x 17" celluloid		
	Gen Diag	Spec Diag	Activity	Gen Diag	Spec Diag	Activity	Gen Diag	Spec Diag	Activity	Gen Diag	Spec Diag	Activity

P	D	N		D	N		B	1a	I	D	N	
Q	D			D			A	2	Q	A	2	I
No of tuberculosis readings	2			1			4			1		
No of "positive" readings	2			2			5			4		
Total number of tuberculosis readings on case 8												

A work card illustrating the assembling of all the readings on each case On the card are twenty boxes in which are noted the readings of the five readers on the four technics. Each reading consists of three parts: a general diagnosis (A or B is tuberculosis, C non tuberculous disease, D essentially negative); a specific diagnosis (1a pulmonary scar, 1b minimal, 2 moderately advanced and 3 far advanced), and the impression of activity (A probably active, Q questionably active and I probably inactive) The illustrated card represents a case with eight readings positive for tuberculosis and thirteen total "positive" readings for tuberculosis and/or nontuberculous disease

This procedure was followed in table 6. For example, there were 171 cases in which there were only one to five positive readings out of a possible twenty. There were an additional 29 in which the number of positive readings was six to ten and 62 cases with eleven or more out of a possible twenty positive readings.

In each one of these classifications the table shows the number of positive readings which were actually obtained on each of the four technics. For example, considering the 62 cases with eleven or more positive readings (underscored row in the table), if a technic were perfect and if the readers were perfect in a nonhuman way there would have been recorded on them a total of 62 × 5, or 310 positive readings. The actual numbers of readings positive for tuberculosis were 259 for the 35 mm., 259 for the 4 by 10 inch, 259 for the 14 by 17 inch paper and 250 for the 14 by 17 inch celluloid films. In other words, all four technics have equal efficiency in selecting these cases that require further study.

When the more liberal definition is used, i. e. when all positive readings (tuberculous and nontuberculous) are counted for these cases (the second part of the table), there is a slight advantage to the 14 by 17 inch celluloid method. The numbers of positive readings in this case were 288 for the 35 mm., 286 for the 4 by 10 inch, 294 for the 14 by 17 inch paper and 303 for the 14 by 17 inch celluloid films. In other words, some supplementary useful detail may be expected on the 14 by 17 inch celluloid films in a small additional number of cases.

A careful review of the table shows that these results are not limited to positive cases as defined by eleven or more positive readings but that they hold with equal force when positive cases are defined by any other number of positive readings. The only exception is that in which the number of positive readings is as low as five or less. A considerable number of these undoubtedly represent occasional overreading or false positives.

TABLE 6.—*Means for Classification*

To show for each technic the number of readings (five readers) that were (a) "positive for tuberculosis" and (b) "positive for tuberculosis and/or nontuberculous disease" when the cases are classified according to the total number of times a case is diagnosed, as "positive for tuberculosis" out of a possible 20 times (five readers on four technics).

			(a) Number of Readings Positive for Tuberculosis (Five Readers) on				(b) Number of Readings Positive for Tuberculosis and/or Nontuberculous Disease (Five Readers) on			
Total Number of Readings Positive for Tuberculosis in All Readings on All Technics	Number of Cases	Maximum Possible Number of Positive Readings on Any One Technic	35 Mm.	4 by 10 Inch Stereo	14 by 17 Inch Paper	14 by 17 Inch Celluloid	35 Mm.	4 by 10 Inch Stereo	14 by 17 Inch Paper	14 by 17 Inch Celluloid
1 - 5	171	855	109	90	49	50	228	210	188	206
6 - 10	29	145	54	54	58	47	96	106	109	101
11 - 13	12	60	36	36	37	37	49	51	53	57
14 - 16	20	100	79	76	75	69	92	87	92	96
17 - 19	9	45	39	42	42	39	42	43	44	45
20	21	105	105	105	105	105	105	105	105	105
11 and over	62	310	259	259	259	250	288	286	294	303

It is important to note here that many additional tables were prepared to test any possible evidence which would limit this method of analysis. For example, it was at first suspected, in view of the rather striking lack of superiority of the 14 by 17 inch celluloid films, that there may have been a tendency for "bunching" of the 14 by 17 inch celluloid readings on positive cases, on which the other technics failed to record any considerable number of positive readings. It was found, however, by all tests that could be devised that this was not the case.[9]

Overreading, or False Positives.—The problem of false positives, or the percentage of films overread, is, of course, also an important consideration in mass survey work. It is probably not as important as underreading, however, because in most survey work a confirmatory 14 by 17 inch celluloid film is taken on all cases called positive by the miniature technics. Nevertheless, considerable inconvenience and anxiety are caused by overreading. It becomes important, therefore, to compare the amount of overreading produced by the different technics. Here again a definition of false positives is required.

One method of defining overreading may be obtained from table 6. It is almost certain, for example, that a case which was called positive by only one reader on only one technic, that is, a case which had only one positive reading out of a possible twenty, is not a case at all but represents overreading. It is more difficult to decide, as the number of positive readings increases, when overreading stops and possible disease begins. However, for the purpose of comparing the different technics for overreading tendencies, it may be sufficient to analyze the cases with five or less positive readings, especially since for cases with more than five positive readings no real difference is apparent between the different technics.

There were 171 cases with five or less positive readings. Specifically, there were 101 cases with only one positive reading, 37 with two, 15 with three, 12 with four and 6 with five positive readings. The smaller the technic the greater was the chance for overreading. For example, of the 101 cases with only one positive reading, 46 were read positive on the 35 mm., 32 on the 4 by 10 inch, 13 on the paper negatives and 10 on the 14 by 17 inch celluloid films. Again, of the seventy-four positive readings on the 37 cases with two positive readings, twenty-one were on the 35 mm., twenty-seven on the 4 by 10 inch, eleven on the paper and fifteen on the celluloid films. The same is true for the other classifications.

Further investigation, however, revealed that by far the greater part of the difference between the technics is attributed to two readers, one of whom read a large number of positives on the 35 mm. (reader *O*), and another who read a large number of apparently false positives on the 4 by 10 inch (reader *M*). For example, of the forty-six false positives on the 35 mm., forty are due to reader *O*, and of the thirty-two single positive readings on the 4 by 10 inch twenty are due to reader *M*. When these readings are neglected, the technics line up in an almost identical way. In other words, it is only because of the tendency of one person that the overreading looms so much larger for each of the miniature technics. Moreover, as may be seen from the second part of table 6, the technics are much more nearly alike even for the group of one to five positive readings under the more liberal definition.

---

[9] A more detailed analysis of this and other points will be presented in subsequent publications.

COMMENT

In evaluating the results of this study, it must be borne in mind that the purpose was to determine the efficiency of the different technics in selecting positive or suggestive cases of tuberculosis; in other words, to determine the efficiency of these technics for case-finding purposes, in identifying in mass surveys the persons requiring further study. It was not set up to determine the efficiency of the different technics in the more detailed and sensitive phases of x-ray work in clinical diagnosis. No doubt the texture and morphology of individual tuberculous lesions are less adequately visualized in the miniature films. This may lead to a certain amount of overreading when miniature films are utilized, and this overreading may constitute a real problem under some circumstances. It was found, however, that the amount of overreading is slight and that it can be traced to only one reader for each of the miniature technics. Therefore, even this slight handicap can apparently be overcome by personal training.

It may therefore be concluded from the foregoing tabulations and analysis that purely from the standpoint of their effectiveness in finding cases of tuberculosis, none of the methods, not even the 14 by 17 inch celluloid, is superior to any of the other methods.

SUMMARY

A Board of Roentgenology was appointed by the administrator of veterans' affairs to study the effectiveness, for tuberculosis case finding, of various roentgenologic and photofluorographic methods.

A 35 mm. photofluorogram, a 4 by 10 inch stereophotofluorogram, a 14 by 17 inch paper negative and a 14 by 17 inch celluloid film were taken, within a few minutes of one another, on each of 1,256 persons. The four sets of films were interpreted independently by two radiologists and three chest specialists. A second independent reading of the 14 by 17 inch celluloid films was obtained from each of the five interpreters.

The material was analyzed in considerable detail as to the variation resulting from the limitations of the various methods as well as from the subjective errors inherent in film interpretation. The results of the analysis justify the conclusions that, except for a slight disadvantage to the miniature technics resulting from overreading, not one of the methods, not even the 14 by 17 inch celluloid, is superior, for case finding purposes, to any of the other methods.

In addition to this conclusion, a number of other recommendations may be derived from this study. These are as follows:

1. The problem of interindividual and intraindividual variation in film interpretation is of such large magnitude that it becomes important to subject this problem to a very extensive and detailed investigation.

2. That a revision of the method of classifying x-rays, including that of the National Tuberculosis Association classification, is needed. Such revision must be based on extensive study and actual experimentation.

3. In mass survey work it is recommended that all survey films be read independently by at least two interpreters. All persons whose films were selected as positive or suggestive for tuberculosis by one or the other of the interpreters should be recalled for further study.

ABSTRACT OF DISCUSSION

DR. L. HENRY GARLAND, San Francisco: I am in complete agreement. The effectiveness of a radiographic method of case finding depends on the interpreters chosen: the more skilled and interested the interpreter, the better the results. The interpreter should choose the film size most practical for the location and the magnitude of the task at hand. Less discrepancy might have transpired in their investigation had the films been read by radiologists familiar with and experienced in the methods used and conservative in their diagnostic conclusions. This is exemplified by the statement that there were "cases which were called moderately advanced tuberculosis on one reading and negative on another." The authors evolved a code for classifying their reports which contains four divisions and sixteen subdivisions; this seems to me rather elaborate for practical use with survey films, especially minifilms. The paper contains numerous references to "films positive for tuberculosis": the unequivocal diagnosis of tuberculosis cannot be made from a film alone; indeed, the pathologist with the gross specimen in his hand often cannot reach such a diagnosis. It would be preferable to use some expression such as "shadows presumably due to tuberculosis." The sentence "on the basis of the 14 by 17 celluloid film interpretations the number of positives varied from 50 to 100" could also be written "on the basis of the 875 cases analyzed the number of positives varied from 6 to 11 per cent." In the light of the methods used, this is not an enormous difference. A group of pathologists with tissue sections or of internists with electrocardiograms would probably show a far greater degree of variation in interpretation. Chest surveys start out as a mass examination procedure but always end up as an individual attempt to reach a medical conclusion from a piece of film—obviously a difficult task except in the presence of well advanced disease. The authors believe that the size of the film used in the survey is relatively unimportant; it is being used merely to select the cases requiring further study. However, the size of the film used in that "further study" is of importance, since it is obvious that the larger the film the better the chance of recording minute or early lesions. Hence, while survey roentgenography of healthy adults can be carried out efficiently with minifilms, clinical diagnostic roentgenography of sick persons requires full size films. All tuberculosis case finding methods are apt to have serious social reverberations if adequate means for treating the case discovered are not planned prior to the survey. Open pulmonary tuberculosis is the prime target in surveys; it is found in about 1 out of every 500 adults in the general population. Being discovered, do we insist on isolation? Often no. Indeed, many persons with positive sputums are still allowed to discharge themselves intermittently from hospitals and sanatoriums. Hence, let us not exhaust our energies on surveys—at least, not until we have adequate treatment arrangements and enforceable isolation regulations.

DR. E. R. LONG, Philadelphia: This report takes some of the sting out of the army mistakes that were made in the diagnosis of tuberculosis. In discussing this question with certain physicians who have asked how many errors the army made at induction stations I have said I thought the error was about 10 per cent in each direction, that is, we excluded 10 per cent that should not have been rejected and made at least a 10 per cent error in the other direction by taking into the army numerous men who should not have been accepted. Dr. Yerushalmy of the U. S. Public Health Service quite properly said, in the light of the study here under discussion, "Ten per cent of what?" I used to think there was at least a theoretical standard of perfection. I remember one occasion when I sat in an induction station reading films with a roentgenologist who was considered one of the top men in the town. There were five 4 by 5 inch films that I had read as showing significant tuberculosis, all of which he had passed as negative. I asked him if we could have 14 by 17 repeats made, and we did. He looked at all the films, saw the shadows that seemed significant to me and made what seemed to me at that time an astonishing remark: "Well, if you want me to read them that way, I will." I am reminded of a statement by my teacher in pathology, H. Gideon Wells, a very wise man with as much experience as any one in this country in the pathology of tumors. He had devoted much of his life to the study, and once, on returning from a meeting with some of the most distinguished investigators, he summarized the discussion for me by saying "The diagnosis of tumors is a matter of taste."

Dr. James M. Flynn, Rochester, N. Y.: May I ask Dr. Chamberlain whether in the reports or interpretations made by these five men the interpretations were short or long? After reading a long report, with no conclusion, you don't know what the man is talking about. He is talking about all sorts of shadows and gives you no conclusions as to whether you are dealing with tuberculosis, virus disease or just some fibrosis that may be occupational. I am anxious to know whether the reports were short or long and to the point, as far as these five interpreters are concerned. There is a great deal of confusion among men today who are sending work to roentgenologists, and I am talking about the referring physician who, after he gets the report, doesn't know what he is dealing with. I should like to know whether these five interpreters made such type reports, and whether when you got through you knew what they were talking about.

Dr. W. Edward Chamberlain, Philadelphia: Dr. Flynn, the statisticians are wonderful people, but they would not be able to work with the kind of report you referred to. We had to school ourselves in being very much to the point. Dr. Garland felt there were too many subclassifications. We have one great advantage in this kind of approach, and that is that we can go ahead and make too many pockets in which we classify these cases. Then the statistician can throw them in together. He can say that pockets 1-a and 2-b and 2-c can be put into one with his tabulating machine. He can set the machine a different way and can run the cards through again, and out comes the answer according to a fewer number of pockets. A great deal of effort went into getting the opinions of these five readers into a form so they could have a great deal of meaning for the statistician; so I don't think we have to plead guilty to having written reports that were misunderstood. Our misunderstandings were of a different order. When we said in our tables "positive for tuberculosis" we did not say it in the sense in which Dr. Garland took it. Unfortunately we had to use a little shorthand. After one has said twenty times "There are some shadows here which one might presume could be due to the tubercle bacillus," then one puts a plus mark in a certain box. That is really what we were doing. We don't say these are tuberculosis. We know some of them were other diseases, but we were simply talking about x-ray shadows. We were trying to compare 35 mm. films with 4 by 10s, with 14 by 17 papers and 14 by 17 celluloids. We think we set up a method by which we can compare those four from the standpoint of case findings, not from the standpoint of resolving power. Dr. Morgan and Dr. Hilleboe have reported that. Concerning that 52 per cent of disagreement among two experienced men, let me point out that it depends on how much detail one goes into in one's interpretation, as to how much disagreement one gets. These men were trying to decide whether a tuberculosis was exudative or fibrocaseous or something else. One will get that disagreement if one tries to decide too many things from a roentgenogram which can't be decided from a roentgenogram. If we try to make a bacteriologic diagnosis from x-ray film we are going to get into trouble. We always do—at least a certain number of times. We are right a certain percentage of the time, and we are also wrong a certain percentage of the time.

Approach to Research.—Scientific observation is not merely the recording of facts; a photographic plate records facts but does not make observations. True observation requires objective accuracy, but it also demands selective discrimination. The scientific observer must observe not only what his senses present to him, aided or unaided by instruments; he must constantly appraise the observations as to correctness and applicability. Facts are not isolated but have numberless connections that extend into infinity. To attempt to observe all of these hides the essential in a dense cloud of the unessential. The investigator discriminates and selects what is pertinent to the particular problem that he wishes to explore.—Sollmann, Torald: Medical Research, Philadelphia, J. B. Lippincott Company, 1946.

UROLOGIC COMPLICATIONS IN INJURY OF THE SPINAL CORD

LIEUTENANT COMMANDER H. CAREY BUMPUS JR. (MC), U.S.N.R.
LIEUTENANT COMMANDER MYRON H. NOURSE (MC), U.S.N.
and
COMMANDER GERSHOM J. THOMPSON (MC), U.S.N.R.

The problems related to the treatment of patients who have received injuries to their spinal cords have always interested physicians. During and after World War I, substantial contributions were made to the knowledge of this subject by Head and Riddoch,[1] Riddoch,[2] Fearnsides [3] and Plaggemeyer.[4] More recently Munro [5] has written extensively on the subject, while Petroff [6] and his associates and Kuhn [7] have reported on the treatment of paraplegic patients in the United States Army hospitals.

Improved methods of rapid transportation following injury and advances in chemotherapy resulting in the advent of the sulfonamide drugs followed by the still more efficient antibiotics, penicillin and streptomycin, together with the more efficient and general use of blood and plasma transfusions, have resulted in the survival of many who formerly would have died a few hours after their injury or, if they survived, would have succumbed to infection a few months later. Because of this increase in the number of survivors, methods of treating the multiple complications of injuries of the spinal cord such as hemothorax, decubitus ulcerations, compound fractures, urinary retention, infection, formation of stone and spasticity with massive muscle reflexes, to mention only a few, have all received greater attention, with more efficient treatment resulting.

From the foregoing list of the commoner complications, one can appreciate that the urologist's part in the treatment of these patients, while of major importance, is no greater than that of many of his associates, especially the neurosurgeons, orthopedic surgeons and officers in charge of physical therapy. This report deals with the urologic complications observed in 101 cases of injury or disease of the spinal cord occurring among United States Navy personnel.

A few of the patients were under observation only a short time prior to their detachment from the service or transfer. The majority, however, are still under observation and treatment by one of us (M. H. Nourse). Included in this series for completeness are 5 cases previously reported.[8]

The most frequent urologic complication of injury of the spinal cord is the so-called cord bladder. In 56

Read before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the United States Navy. The opinions and views set forth in this article are those of the authors and are not to be considered as reflecting the policies of the Navy Department.

of the patients this vesical dysfunction followed gunshot or shrapnel wounds received at Saipan, Iwo Jima or Okinawa. In 34 it resulted from fractures of the spinal column incident to the hazards of service such as airplane accidents, falls down hatches and smashing up in jeeps. Among 11 other patients, the vesical paralysis was the result of tumors of the spinal cord in 2, followed inflammatory disease in 5, developed insidiously after eighteen months in a Japanese concentration camp in 1 (probably from a dietary deficiency), was associated with myelodysplasia in 1 and a protruding intervertebral disk in another and was the aftermath of spinal anesthesia in 1.

The height of the lesion in the cord has a distinct bearing on the urologic complications. Lesions above the conus medullaris, in which physiologists and neurologists place the mechanism of the bladder reflex and which anatomists place close to the eleventh and twelfth thoracic vertebrae, involve the pathways of inhibitory impulses from the higher centers. Injuries which occur at the conus or below, in the cauda equina, do not interfere with these inhibitory tracts but damage only the reflex arc.

Perhaps of more importance than the level of the lesion is whether it is complete or incomplete. The sparing of nerve tracts and late recovery of the ability to transmit impulses account for unpredictable improvement in many cases.

In temporary block or shock of the spinal cord, vesical function returns to normal within a few weeks. Such cases are exceptional, and none are included in this study. In our series, after many weeks and, in some cases, months of convalescence, in several patients vesical function became comparatively normal, but in the great majority only two types of neurogenic vesical dysfunction were demonstrable. There was either an automatic or a reflex type of bladder, in which the lesion was as a rule above the tenth thoracic vertebra, or a retention bladder with overflow incontinence, in which the injury was usually below the tenth thoracic vertebra and generally involved the cauda equina.

The type of dysfunction following lesions low in the spinal column that usually involve the cauda equina is the most responsive to transurethral resection. Examinations through the cystoscope show various degrees of relaxation of the neck of the bladder. In some there is a constriction in the region of the internal urethral orifice so that the bladder and dilated prostatic urethra have an hourglass appearance. In other cases, a bar type of deformity and in others an appearance like that of the vocal cords is seen.

In all cases the vesical wall is trabeculated. This is an evidence of hypertrophy that can develop only as a result of increased work in the efforts of the bladder to empty, as happens in the case of urinary obstruction following prostatic hypertrophy. In this series of cases, however, the prostate can definitely be excluded as the cause of the obstruction and trabeculation, for only 3 of the patients were more than 40 years of age, 14 were in their thirties, 61 in their twenties and 23 in their teens.

In these young patients tissue is resected from the entire circumference of the vesical neck, enough being removed to make a definite funnel of the prostatic urethra, postoperative retention depending, as after prostatectomy, on the external sphincter. To do this requires the removal of but a small amount of tissue. If the first resection does not produce the desired effect, multiple operations are indicated, although the total amount of tissue excised seldom exceeds 10 Gm. In 16 cases of our series multiple resections were employed.

Of 39 patients whose injury was at or below the level of the eleventh thoracic vertebra and for whom transurethral resection was performed, 36 now have voluntary urination. They can empty the bladder completely by straining, they sleep through the night without voiding and they have no incontinence. All these patients can tell when the bladder is full, although the sensation which they feel is not normal. They describe it as a dull ache or heavy feeling in the lower part of the abdomen. Unusually large vesical capacity is present in some cases. One patient passed 925 cc. at one voiding. Two patients void automatically. Another, whose lesion involved the twelfth thoracic vertebra, fails to void after three transurethral resections. The bullet which injured his cord also injured his right kidney, which was removed transabdominally. As a result he has extremely weak muscles on the right side of his abdomen and cannot exert the abdominal pressure that is necessary to void. Intact abdominal muscles are a great help in the act of urination in paraplegic patients as well as in normal persons. The vesical neck of this patient, on being examined through the cystoscope, appeared wide open, and yet no urine can pass, even with extreme manual pressure. He has been taught to catheterize himself and has no incontinence even when he permits as much as 1,000 cc. of urine to accumulate.

Transurethral resection has been of much benefit, although not so spectacular, in patients having lesions high in the spinal column in whom an automatic or reflex bladder has been established but one which is inefficient in that it does not empty completely. Thus reflex stimulation might occur when the bladder contains 400 cc. and voiding takes place. If, however, 200 cc. of residual urine remains after voiding, one must class this as an inefficient type of automatic bladder. The patient is deprived of the full reservoir function of his bladder. If, in some way, the bladder can be made to empty completely, the interval of time between reflex urinations can be doubled. In 19 of these patients transurethral resection has diminished or entirely abolished the amount of residual urine, and, in cases in which previously it had been impossible to free the urine of infection, now in almost all these cases the urine has become crystal clear and finally sterile.

Such operations have never produced incontinence. To the contrary, they tend to relieve it, for, given longer intervals between automatic voiding, many of these patients have acquired an uncanny ability to time the emptying of the bladder and seldom soil themselves. In 14 of these patients with efficient automatic bladder, voiding occurs at three to four hour intervals, depending on fluid intake. If they do not drink too much in the evening they go through the night perfectly dry. Catheterization of these patients after voiding shows no residual. The patients with lesions of the cauda equina who do not have reflex type of urination practically never suffer any leakage unless they strain too hard when exercising or working, when urine may be forced from the bladder.

Of equal importance with vesical dysfunction as a complication of injury of the spinal cord is the incidence of infection in both the urinary and the genital tract. The type of drainage that is employed is the determining factor of its incidence. Until such time as the bladder has recovered whatever emptying and retaining function it is going to regain after the initial injury, the question experience as any one in this country in the pathology of tumors. He had devoted much of his life to the study, and once, on returning from a meeting with some of the most distinguished investigators, he summarized the discussion for me by saying "The diagnosis of tumors is a matter of taste."

Dr. James M. Flynn, Rochester, N. Y.: May I ask Dr. Chamberlain whether in the reports or interpretations made by these five men the interpretations were short or long? After reading a long report, with no conclusion, you don't know what the man is talking about. He is talking about all sorts of shadows and gives you no conclusions as to whether you are dealing with tuberculosis, virus disease or just some fibrosis that may be occupational. I am anxious to know whether the reports were short or long and to the point, as far as these five interpreters are concerned. There is a great deal of confusion among men today who are sending work to roentgenologists, and I am talking about the referring physician who, after he gets the report, doesn't know what he is dealing with. I should like to know whether these five interpreters made such type reports, and whether when you got through you knew what they were talking about.

Dr. W. Edward Chamberlain, Philadelphia: Dr. Flynn, the statisticians are wonderful people, but they would not be able to work with the kind of report you referred to. We had to school ourselves in being very much to the point. Dr. Garland felt there were too many subclassifications. We have one great advantage in this kind of approach, and that is that we can go ahead and make too many pockets in which we classify these cases. Then the statistician can throw them in together. He can say that pockets 1-a and 2-b and 2-c can be put into one with his tabulating machine. He can set the machine a different way and can run the cards through again, and out comes the answer according to a fewer number of pockets. A great deal of effort went into getting the opinions of these five readers into a form so they could have a great deal of meaning for the statistician; so I don't think we have to plead guilty to having written reports that were misunderstood. Our misunderstandings were of a different order. When we said in our tables "positive for tuberculosis" we did not say it in the sense in which Dr. Garland took it. Unfortunately we had to use a little shorthand. After one has said twenty times "There are some shadows here which one might presume could be due to the tubercle bacillus," then one puts a plus mark in a certain box. That is really what we were doing. We don't say these are tuberculosis. We know some of them were other diseases, but we were simply talking about x-ray shadows. We were trying to compare 35 mm. films with 4 by 10s, with 14 by 17 papers and 14 by 17 celluloids. We think we set up a method by which we can compare those four from the standpoint of case findings, not from the standpoint of resolving power. Dr. Morgan and Dr. Hilleboe have reported that. Concerning that 52 per cent of disagreement among two experienced men, let me point out that it depends on how much detail one goes into in one's interpretation, as to how much disagreement one gets. These men were trying to decide whether a tuberculosis was exudative or fibrocaseous or something else. One will get that disagreement if one tries to decide too many things from a roentgenogram which can't be decided from a roentgenogram. If we try to make a bacteriologic diagnosis from x-ray film we are going to get into trouble. We always do—at least a certain number of times. We are right a certain percentage of the time, and we are also wrong a certain percentage of the time.

Approach to Research.—Scientific observation is not merely the recording of facts; a photographic plate records facts but does not make observations. True observation requires objective accuracy, but it also demands selective discrimination. The scientific observer must observe not only what his senses present to him, aided or unaided by instruments; he must constantly appraise the observations as to correctness and applicability. Facts are not isolated but have numberless connections that extend into infinity. To attempt to observe all of these hides the essential in a dense cloud of the unessential. The investigator discriminates and selects what is pertinent to the particular problem that he wishes to explore.—Sollmann, Torald: Medical Research, Philadelphia, J. B. Lippincott Company, 1946.

UROLOGIC COMPLICATIONS IN INJURY OF THE SPINAL CORD

LIEUTENANT COMMANDER H. CAREY BUMPUS JR. (MC), U.S.N.R.
LIEUTENANT COMMANDER MYRON H. NOURSE (MC), U.S.N.
and
COMMANDER GERSHOM J. THOMPSON (MC), U.S.N.R.

The problems related to the treatment of patients who have received injuries to their spinal cords have always interested physicians. During and after World War I, substantial contributions were made to the knowledge of this subject by Head and Riddoch,[1] Riddoch,[2] Fearnsides [3] and Plaggemeyer.[4] More recently Munro [5] has written extensively on the subject, while Petroff [6] and his associates and Kuhn [7] have reported on the treatment of paraplegic patients in the United States Army hospitals.

Improved methods of rapid transportation following injury and advances in chemotherapy resulting in the advent of the sulfonamide drugs followed by the still more efficient antibiotics, penicillin and streptomycin, together with the more efficient and general use of blood and plasma transfusions, have resulted in the survival of many who formerly would have died a few hours after their injury or, if they survived, would have succumbed to infection a few months later. Because of this increase in the number of survivors, methods of treating the multiple complications of injuries of the spinal cord such as hemothorax, decubitus ulcerations, compound fractures, urinary retention, infection, formation of stone and spasticity with massive muscle reflexes, to mention only a few, have all received greater attention, with more efficient treatment resulting.

From the foregoing list of the commoner complications, one can appreciate that the urologist's part in the treatment of these patients, while of major importance, is no greater than that of many of his associates, especially the neurosurgeons, orthopedic surgeons and officers in charge of physical therapy. This report deals with the urologic complications observed in 101 cases of injury or disease of the spinal cord occurring among United States Navy personnel.

A few of the patients were under observation only a short time prior to their detachment from the service or transfer. The majority, however, are still under observation and treatment by one of us (M. H. Nourse). Included in this series for completeness are 5 cases previously reported.[8]

The most frequent urologic complication of injury of the spinal cord is the so-called cord bladder. In 56

Read before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

of the patients this vesical dysfunction followed gunshot or shrapnel wounds received at Saipan, Iwo Jima or Okinawa. In 34 it resulted from fractures of the spinal column incident to the hazards of service such as airplane accidents, falls down hatches and smashing up in jeeps. Among 11 other patients, the vesical paralysis was the result of tumors of the spinal cord in 2, followed inflammatory disease in 5, developed insidiously after eighteen months in a Japanese concentration camp in 1 (probably from a dietary deficiency), was associated with myelodysplasia in 1 and a protruding intervertebral disk in another and was the aftermath of spinal anesthesia in 1.

The height of the lesion in the cord has a distinct bearing on the urologic complications. Lesions above the conus medullaris, in which physiologists and neurologists place the mechanism of the bladder reflex and which anatomists place close to the eleventh and twelfth thoracic vertebrae, involve the pathways of inhibitory impulses from the higher centers. Injuries which occur at the conus or below, in the cauda equina, do not interfere with these inhibitory tracts but damage only the reflex arc.

Perhaps of more importance than the level of the lesion is whether it is complete or incomplete. The sparing of nerve tracts and late recovery of the ability to transmit impulses account for unpredictable improvement in many cases.

In temporary block or shock of the spinal cord, vesical function returns to normal within a few weeks. Such cases are exceptional, and none are included in this study. In our series, after many weeks and, in some cases, months of convalescence, in several patients vesical function became comparatively normal, but in the great majority only two types of neurogenic vesical dysfunction were demonstrable. There was either an automatic or a reflex type of bladder, in which the lesion was as a rule above the tenth thoracic vertebra, or a retention bladder with overflow incontinence, in which the injury was usually below the tenth thoracic vertebra and generally involved the cauda equina.

The type of dysfunction following lesions low in the spinal column that usually involve the cauda equina is the most responsive to transurethral resection. Examinations through the cystoscope show various degrees of relaxation of the neck of the bladder. In some there is a constriction in the region of the internal urethral orifice so that the bladder and dilated prostatic urethra have an hourglass appearance. In other cases, a bar type of deformity and in others an appearance like that of the vocal cords is seen.

In all cases the vesical wall is trabeculated. This is an evidence of hypertrophy that can develop only as a result of increased work in the efforts of the bladder to empty, as happens in the case of urinary obstruction following prostatic hypertrophy. In this series of cases, however, the prostate can definitely be excluded as the cause of the obstruction and trabeculation, for only 3 of the patients were more than 40 years of age, 14 were in their thirties, 61 in their twenties and 23 in their teens.

In these young patients tissue is resected from the entire circumference of the vesical neck, enough being removed to make a definite funnel of the prostatic urethra, postoperative retention depending, as after prostatectomy, on the external sphincter. To do this requires the removal of but a small amount of tissue. If the first resection does not produce the desired effect, multiple operations are indicated, although the total amount of tissue excised seldom exceeds 10 Gm. In 16 cases of our series multiple resections were employed.

Of 39 patients whose injury was at or below the level of the eleventh thoracic vertebra and for whom transurethral resection was performed, 36 now have voluntary urination. They can empty the bladder completely by straining, they sleep through the night without voiding and they have no incontinence. All these patients can tell when the bladder is full, although the sensation which they feel is not normal. They describe it as a dull ache or heavy feeling in the lower part of the abdomen. Unusually large vesical capacity is present in some cases. One patient passed 925 cc. at one voiding. Two patients void automatically. Another, whose lesion involved the twelfth thoracic vertebra, fails to void after three transurethral resections. The bullet which injured his cord also injured his right kidney, which was removed transabdominally. As a result he has extremely weak muscles on the right side of his abdomen and cannot exert the abdominal pressure that is necessary to void. Intact abdominal muscles are a great help in the act of urination in paraplegic patients as well as in normal persons. The vesical neck of this patient, on being examined through the cystoscope, appeared wide open, and yet no urine can pass, even with extreme manual pressure. He has been taught to catheterize himself and has no incontinence even when he permits as much as 1,000 cc. of urine to accumulate.

Transurethral resection has been of much benefit, although not so spectacular, in patients having lesions high in the spinal column in whom an automatic or reflex bladder has been established but one which is inefficient in that it does not empty completely. Thus reflex stimulation might occur when the bladder contains 400 cc. and voiding takes place. If, however, 200 cc. of residual urine remains after voiding, one must class this as an inefficient type of automatic bladder. The patient is deprived of the full reservoir function of his bladder. If, in some way, the bladder can be made to empty completely, the interval of time between reflex urinations can be doubled. In 19 of these patients transurethral resection has diminished or entirely abolished the amount of residual urine, and, in cases in which previously it had been impossible to free the urine of infection, now in almost all these cases the urine has become crystal clear and finally sterile.

Such operations have never produced incontinence. To the contrary, they tend to relieve it, for, given longer intervals between automatic voiding, many of these patients have acquired an uncanny ability to time the emptying of the bladder and seldom soil themselves. In 14 of these patients with efficient automatic bladder, voiding occurs at three to four hour intervals, depending on fluid intake. If they do not drink too much in the evening they go through the night perfectly dry. Catheterization of these patients after voiding shows no residual. The patients with lesions of the cauda equina who do not have reflex type of urination practically never suffer any leakage unless they strain too hard when exercising or working, when urine may be forced from the bladder.

Of equal importance with vesical dysfunction as a complication of injury of the spinal cord is the incidence of infection in both the urinary and the genital tract. The type of drainage that is employed is the determining factor of its incidence. Until such time as the bladder has recovered whatever emptying and retaining function it is going to regain after the initial injury, the question of drainage is paramount. In only 1 case of this series could manual expression of the urine be done efficiently. In 19 cases suprapubic cystostomy was used at some stage in convalescence; in others retention was cared for by urethral catheters.

Here it is well to stress that small catheters are preferable to large ones; a no. 18 Foley bag type is ideal. Many of the patients have periodic priapism, and the Foley catheter is the only type which will stay in proper adjustment. The catheters were changed frequently and irrigated regularly. Tidal drainage was used in the majority of the cases at some time during convalescence, but it was not used in all nor was it used continuously. It was found that irrigations at least three times a day and once at night with a piston syringe kept the bladder cleaner than did tidal irrigation alone. Puddling of the infected urine and calcium debris occurred in spite of the most careful efforts to maintain efficient automatic drainage. In our experience, the avoidance of infection is a more important measure in maintaining an elastic bladder than rhythmic exercise.

In the first few weeks following injury the use of a urethral catheter, if it can be properly maintained, is the easiest method of caring for vesical drainage. Under combat conditions if nursing facilities are not adequate or in cases in which drainage will be necessary late into convalescence, suprapubic drainage is preferable, as the incidence of five periurethral abscesses, three fistulas and several cases of epididymitis among our patients suggests.

A fairly frequent compelling cause for the use of catheter drainage is spasticity, with its associated massive muscle spasms in which the thighs automatically and suddenly jerk up onto the abdomen. A urinal under these conditions is constantly being upset in the bed, and it is of little use. Such spasticity is usually associated with spasticity of the detrusor muscles, so that the use of the bladder as a reservoir is extremely limited.

To increase the capacity of the bladder and to try to overcome its spasticity, tidal drainage was used early in convalescence. Periodically the catheter was removed when the outflow limb of the device for tidal drainage had been gradually raised over a period of weeks to a level well above the bladder. Oftener than not, when the catheter was removed the patient voided automatically and with fair efficiency. This occurred most quickly in cases in which the injury was high in the spinal column, above the tenth thoracic vertebra. When there was decided general spasticity the vesical capacity rapidly diminished, and not until the spasticity was overcome did it increase or remain as great as when the tidal drainage was first discontinued.

Such spasticity is considered by some authorities to be the result of nerve irritation at the site of injury; therefore, thorough laminectomy as early as feasible seems indicated in every traumatic lesion. Laminectomy is a difficult operation to do on the beach or aboard ship, and only a few were done under these conditions. Therefore the majority of the fifty-three laminectomies performed in our series of 101 cases were done after the patients' arrivals at the base. Seeing the removal of spicules of bone, fragments of metal and pieces of uniform from the dural sac result in relief of pain, diminution of spasticity and improvement of nerve function has convinced us that the teaching that late laminectomy is of slight value is regrettable. As the risk of such an operation is slight, it is, in our opinion, a grave error to deny the patient the benefit of even the slightest gain in neural function because some have thought that a limit of time exists beyond which neural regeneration is impossible and neurosurgical intervention is fruitless.

Hypercalcinuria inevitably ensues when prolonged recumbency is required. How rapid the transfer of calcium from the skeleton to the urine is can be appreciated only by the viewing of roentgenograms that are taken at regular intervals and watching of the patient's urine, which becomes clouded with calcium debris, mucus and pus. Keeping this mass from coalescing in the urinary tract to form stones becomes one of the major problems in the care of these patients, and the removal of stones, once they have formed, becomes an important task.

Removal of stones from the bladder is not difficult, especially if the patients who have residual urine are examined at regular intervals. Small vesical stones will be detected early in their formation and can be washed out through the cystoscope. In 67 of our cases they developed.

To prevent this formation of stones in the bladder and kidney, a daily intake of 4,000 cc. was forced in order to keep the urinary salts in as great dilution as possible. The ingestion of large amounts of either milk or fruit juices was discouraged. All our patients were encouraged to get out in the sun and acquire a deep tan. There was no indication that this increased formation of stones.

Patients who have lesions high in the spinal cord do not suffer with renal colic, and the only evidence of a stone passing down the ureter may be high temperature. Therefore the habit of making excretory urograms periodically was established. Any indication of obstruction of the upper part of the urinary tract was met by immediate ureteral catheterization. In 11 cases stones were found in one kidney and in 8 cases in both kidneys, and in some of these cases stones were also present in the ureters.

In the conclusion of a report on complications following injuries of the spinal cord, it would seem fitting to summarize the present status of this group of 101 patients. Two have died, but in neither case did the death follow surgical treatment; in 1 case the death was sudden and unexplained; the other death, which occurred three hundred and sixty-nine days after injury, was the result of multiple decubitus ulcers. Fifty-eight patients have undergone transurethral resection; in 57 cases the results of operation were successful, but in 1 case the result was a total failure. Only 6 patients are now dependent on catheters; the other 93 can pass their urine without mechanical assistance of any kind. Of this number, 53 have a voluntary type of urination, while in 40 it is automatic. In 85 cases the urine is grossly clean, and in 39 cases cultures have been sterile.

ABSTRACT OF DISCUSSION

Dr. Miley B. Wesson, San Francisco: This paper is unusual from a number of standpoints. First, it calls attention to the fact that it requires a war to furnish the material for an authentic paper on neurogenic bladder. Second, the subject is not going to be thoroughly clarified until more work is done in the underlying basic sciences—anatomy and physiology. And, third, intelligently riding a hobby may result in an epoch-making discovery. Sir John Thompson-Walker advocated suprapubic cystotomy for neurogenic bladder in his Hunterian lecture in 1917. His paper was based wholly on theory, and he told me in Budapest in 1936 that he was much disappointed in the clinical results. Following World War I, men with cord bladders were concentrated at Walter Reed Hospital and there were studied by Plaggemeyer and Cummings. They found that the best results were obtained by following

Hugh H. Young's orders to the urologists of the American Expeditionary Forces—to leave the uninfected bladders alone, and they would empty spontaneously. Over twenty-five years ago, Dr. Young started me on so-called three weeks' study of the vesical trigone, and I worked three years on the embryology, anatomy, physiology and pharmacology of the bladder neck. Our knowledge of the physiology is still sketchy and more or less inaccurate. In 1921, Corbus and O'Conor published a beautiful paper on neurogenic bladders, in which the retention was due to a median bar or hypertrophied trigone. Unfortunately, Young's punch had not then been wired for electricity so as to control hemorrhages, and no operation was done. Now, after World War II, our essayists, whose surgical hobby is the use of the modernized Young punch, are successfully treating such patients. If Dr. Young were here, I believe that he would approve of our essayists' operation, because it is scientifically sound, being merely the weakening of a sclerotic internal sphincter so that the trigone muscle can pull it open.

Dr. Willet F. Whitmore, New York: My familiarity with the problem is based on a year of recent experience at the Bronx Veterans Administration Hospital, in New York. During that period, 90 paraplegic patients came under my observation. The goal of rehabilitation of patients with urologic disorders is to establish some form of socially manageable urethral voiding which will efficiently empty the bladder of sterile or at least grossly clear urine and, at the same time, minimize the occurrence of urinary infection and its complications. Following urologic investigation the first step is the closure of the urinary fistulas. Two to four weeks after the fistula had closed, the patient is placed on tidal irrigation for an arbitrary period of from two to six months. Less than 10 per cent of our patients showed any increase in capacity of the bladder or any change in bladder function, as evidenced by the cystometric study, during this period of tidal irrigation. At the end of this time, the urethral catheter is removed and the success or failure of voiding observed. The cystometric study rarely permits an accurate appraisal of what is going to happen when the catheter is removed. In 90 patients there were 2 deaths, neither from disorders of the urinary tract. Of the remaining 88 patients, 71 are voiding, 11 have urethral catheters and 6 have suprapubic cystostomies. Of the 71 patients who are voiding, 36 have a satisfactory result and 35 still present problems for one reason or another; 13 patients have had transurethral resections, with good results in 9 instances.

Dr. Grayson Carroll, St. Louis: This presentation of treatment of urologic complications in injuries of the spinal cord is a valuable contribution to the care of patients with these difficult conditions. My colleagues and I have carried out this procedure in a number of selected cases and have been gratified with the results obtained. I should like to ask Dr. Nourse what is the cause of the obstruction at the bladder neck. Dr. Emmett has ventured the opinion that it is hypertrophic tissue caused by the multiple efforts at voiding. He has seen cases in which evidence of back pressure was noted, such as coarse trabeculations, and has demonstrated the presence of hypertrophic tissue by pathologic examination of the tissue removed. In some 30 cases of spinal injury studied at the Veterans Hospital in St. Louis, we were surprised to find that so many of the urethrocystograms showed a widening at the bladder neck, giving a funnel-shaped picture which pointed to the internal sphincter but wide at the internal sphincter. This gave the impression that the internal sphincter was broader than normal and therefore required no resection. I should like to ask Dr. Thompson or Dr. Nourse whether their urethrocystograms gave the same picture.

Lieutenant Commander Myron H. Nourse (MC), U. S. N.: Dr. Carroll, in regard to what it is that causes the hypertrophy, from our experience it seems to be an effort of the bladder to empty itself against an obstructed bladder neck. The demonstration of the obstruction is seen with a McCarthy panendoscope with a small sheath. Many of these cannot be seen unless the bladder is distended with water. As the bladder distends, the contraction ring about the area of the internal ureteral orifice can be seen to contract. In many of them it appears just as an iris diaphragm. The tissue that is resected microscopically is shown to be hypertrophied muscle tissue. The resection includes the entire bladder neck to the verumontanum and sometimes distal. Many times we find that tissue taken distal to the verumontanum seems to be as obstructive as the rest. It is a complete conization, just as is shown on the cystograms and on the slides. All hypertrophied muscle tissue and necrotic inflammatory tissue is removed.

PSYCHIC FACTORS IN THE DEVELOPMENT AND TREATMENT OF OBESITY

S. CHARLES FREED, M.D.
San Francisco

While there might be doubt as to the shortening of life by such factors as smoking, tobacco, alcohol and exercise, there is unanimous agreement of all authorities that overweight has a decided effect on decreasing the span of life. Statistics overwhelmingly show that overweight not only results in increased death rate but is also responsible for the earlier development of cardiovascular-renal diseases, diabetes and even cancer. It is, therefore, surprising that with this knowledge the members of the medical profession have been so lightly interested in a concerted and sincere effort to treat obesity or to prevent its occurrence. Heroic measures which involve tremendous expense, labor and time have been expended in the prevention and treatment of infectious diseases, nutritional disturbances and cancer, and great publicity has been given to such efforts. The common cold also has received widespread attention in newspapers, magazines and medical publications because of the economic factors involved in the loss of work hours. In contrast, overweight is discussed only occasionally, and education of the public in this regard is sadly neglected, although the prevention or treatment of obesity has a far greater benefit in increasing the life span and combating degenerative changes than that of practically any other disease or dysfunction.

For many decades physicians have been taught that obesity is a glandular or metabolic disturbance; that the obese person therefore differs from the one of normal weight in regard to his "glandular balance" or his fat or carbohydrate metabolism, and various theories have been proposed to account for one person being heavier than another. These theories have all been effectively refuted by Newburgh[1] and others[2] who, in thorough investigations, have been unable to find in the great majority of obese persons any alterations in endocrine or metabolic behavior from normal. The conclusion is warranted that overweight is simply due to a positive caloric balance and that these persons eat more food than they expend in the form of energy. It is true, however, that one person will have a positive caloric balance on a diet of 1,500 calories and another will have a negative balance, so that one will gain weight and the other will lose weight. Human machines, like other machines, may differ in efficiency, and the

metabolically efficient human body will gain weight on the same intake of food on which the inefficient one will lose weight. This efficiency is directly related to the nervous system of the body and involves, in various persons, the ability to relax and be completely at rest, the performance of wasteful movements, muscular tensions and intensity of activity. Every one knows persons who can never sit still and are constantly in motion and others who have the ability to remain motionless for long periods of time. It is obvious that the energy expenditure of two such persons will differ greatly and thus account for the loss of weight in one and the gain of weight in the other, even though they partake of similar diets.

Thus it is readily recognized that the personality of a subject will control to varying extents the expenditure of energy. It is also being increasingly recognized that personality will likewise influence the intake of food. Psychiatrists have long known that eating is an emotional outlet and may be under the influence of the subconscious mind. This article is therefore an attempt to bring to physicians, who are often called on to treat obesity, the usual psychic factors which control the patient's appetite or render him unable to check the urge to eat in order to maintain weight. It is not intended to completely review these psychic factors, which is the task of the psychiatrist, but this brings to the attention of the general physician the existence of such influences, many of which can be controlled without formal psychotherapy, and demonstrates how these patients can be treated from this point of view in a far more successful way than has been accomplished on the so-called "glandular" basis.

FACTORS IN OVEREATING

There are a variety of psychologic factors which intensify the appetite for food. Many of these are unconscious, while others are recognized by the patients and can be controlled by them. Where the urge to eat is dependent on unconscious tensions, it is difficult for the patient to restrict the intake of food. Some of these unconscious drives are so powerful that no incentive for weight reduction, not excepting the threat of early death, can induce the patient to refrain from overeating. Not uncommonly a patient will say "I would rather die than starve." This attitude is much the same as that of the repentant alcoholic addict who realizes that he is a social disgrace but can do little to control his appetite for alcohol. The tobacco habit is similarly controlled with difficulty, even though a patient may be advised that it is injurious to his health.

In general, it may be said that anything which increases the emotional tonus, such as sorrow, nervousness, irritability, anxiety or an emotional upset, will further the desire for food and cause an increase in weight in many persons who have a tendency to be obese. This is shown by the following data. Five hundred consecutive patients who requested treatment for their overweight were asked the question "When you are nervous or worried do you eat more or less?" Three hundred and seventy answered that they either ate larger meals or ate more frequently, 95 of the remaining 130 answered that they did not believe that they ate more when nervous or worried but that they did eat more when they were idle, bored or tired. The remainder claimed that their appetites were always good, or that they just enjoyed food.

It is obviously impossible for all overweight patients to consult psychiatrists regarding fundamental causes of the drive or craving for food beyond normal amounts. A great majority of patients may be helped however by the physician who attempts to understand the reasons for their overeating. It is surprising to find that many superficial conditions may be the inciting factors in the urge to eat excessively. Furthermore, it will be shown that whatever glandular factor may be responsible for overeating work not by direct biochemical action on the metabolism of fat but by increasing nervous tension. The following conditions, many of which are capable of being treated by the general physician, have been found to result in overeating.

1. *Environment.*—The child who is brought up in a family where it is common to have large, rich meals will imitate the habits of those around him by eating an excessive amount of food. Such cases are found in families in which all members are overweight. People who are entertaining or are being entertained to a great extent, such as businessmen who conduct their affairs over the dinner table, are constantly exposed to rich foods and are influenced by suggestion to overeat.

2. *Economics.*—In impoverished homes food is a prominent feature in the daily life of a person because of the relative insecurity of the supply of food from day to day. The importance of sustenance creates an aggressiveness toward food, which results in eating all that is available (usually the inexpensive, high caloric types of food). Children are also impressed with the competition for food and the necessity for seizing all that is possible as well as with the importance of not wasting or leaving any. These habits may persist even after wealth is obtained.

3. *Monotony.*—Where there is a lack of interests or distractions escape is sought in eating. This occurs in housewives who break the daily routine by frequent feeding. It is also seen in such persons as traveling salesmen, who drive long distances and vary the monotony of their trips by stopping for food every hour or so. A great number of people overeat on weekends, when they are idle and away from the distracting influences of their work.

4. *Occupation.*—Those employed in restaurants, candy shops, delicatessen stores and the like are constantly influenced to eat by the presence of food.

5. *Organic Diseases.*—Patients who are bedridden or whose activities are restricted by a disability, such as a fracture or convalescence from a surgical operation, will probably eat according to the habits established when they were active and will thus put on weight because of the temporary decrease in their expenditure of energy. Such a condition as simple anemia, which induces fatigue, will also result in a condition of inertia and relative overeating. The tendencies here might actually be listed under the heading of monotony or nervousness, since many persons with anemia will become irritable and nervous, and the bedridden patient is also subject to monotony.

6. *Nervousness.*—In a broad sense, that which makes a patient worried or anxious, such as a social upset, domestic difficulty or illness in the family, will result

in overeating through the increase in his psychic hunger. It is not uncommon that after the death of a member of the family the others will find themselves getting heavier, much to their consternation and shame, because loss of weight is considered a classic response to such an occurrence.

7. *Glandular Imbalance.*—The glandular dysfunctions which result in overweight are hardly those which have been taught for years in medical schools, which teaching is reflected in the traditional treatment of obese patients by thyroid or injections of such preparations as pituitary extracts. In only rare cases is obesity of endocrine origin. Some glandular conditions may, however, indirectly lead to increased appetite. The two most common endocrine dysfunctions found to be responsible for overeating are the climacteric, which results in an increased nervous tension and thus leads to overeating, and premenstrual tension, which also increases tension but which occurs only for about one week before menstruation. Puberty and pregnancy are conditions which commonly precipitate overeating through the development of anxieties, fears and new drives. The administration of thyroid for the reduction of overweight is in the great majority of cases without an adequate scientific basis. Many patients may actually gain weight on thyroid therapy because their appetite becomes greater as the result of increased nervous tension induced by the medicament.

8. *Subconscious Factors.*—Among subconscious factors there is a variety of patterns which may result in overweight. Frustrations, overcompensations and lack of emotional satisfaction are commonly associated with overeating. Often patients, especially women, will escape from social competition or responsibility by "retreating behind the wall of obesity." This group probably requires psychotherapy of a fundamental type in order to release the patient from the drive to eat. In this type of patient there is probably, as many psychiatrists believe, a regression toward the infantile state with an increased drive for oral satisfaction by appeasing the suckling instinct. This same drive is probably present to greater or lesser degrees in most patients with a tendency to overeat but becomes extreme and uncompensated in some of them.

The above classification is not intended as a formal or accurate analysis of those psychic factors which tend to prevent the patient from maintaining his proper weight. There is considerable overlapping and interrelationship of the various groups. The separation into these different headings is an arbitrary but practical one from the point of view of treatment by the general practitioner.

It is not considered that these factors are specific causes for overeating but simply that they influence the release of nervous energy into the channel of overeating in those persons who tend in that direction. The same psychic factors will produce in other subjects various types of psychosomatic disorders, such as colitis, gastric ulcers and neurogenic dermatoses. The fundamental reasons why persons have a tendency to overeat has been extensively discussed by psychiatrists and others.[3] A large percentage of obese persons had a delayed emotional maturity, as shown by the fact that as children enuresis occurred in 40 per cent. Such children also had an extremely poor sense of self expression and sought entertainment in passive pleasures, such as music and radio. Often this was due to overprotection of the child by the parent. Thus, the tendency of the children to inactivity brought on their overeating, rather than the obesity producing inactivity. Many children had parents who were in constant conflict with open hostility, although often there was a compensating violent display of affection and concern. In many, however, overeating did not appear until adulthood, when responsibilities and insecurity brought out these latent characteristics developed in childhood.

TREATMENT

The treatment of obesity involves the understanding of the patient from a physical as well as a psychologic point of view. A complete examination of the patient should be made in order to determine any organic change which might cause increased irritability or nervous tension. Such conditions as simple anemia, arthritis, premenstrual tension, menopause and postoperative asthenia may all result in relative overeating, and treatment should be instituted in accordance with the disturbance. If the nervous irritability is of a temporary nature, such as, for example, the worry over a child's illness, unpleasantness at work or a domestic rift, sedation with a barbiturate compound is helpful. Where the emotional tension is due to a deeper and stronger influence the patients should be studied in accordance with their background, upbringing and present family relationship in an effort to determine the cause for the increased desire for food from a psychologic point of view. The physician can often determine the cause and explain to the patients the actual reasons for their excessive desire for food, thereby aiding them significantly in their efforts to combat this reaction. While such studies are being made and treatment is being instituted for the various disturbances which may be found, it is well to have these patients start immediately on their reduction diet.

The diet should be a well balanced one of 800 to 1,100 calories. The drug of choice to suppress their desire for food is amphetamine sulfate, or, as it is commercially known, Benzedrine sulfate. This compound is of inestimable value in controlling the desire for food and reducing the level of satiability to a more normal one.[4] This drug is commonly administered in dosages of 5 mg. three times a day, thirty to sixty minutes before each meal. Occasionally patients will require 10 mg. at one or more times during the day, depending on their response to the drug. Only rarely does amphetamine fail to curb the appetite, except in those whose drive for food is overpowering and who probably require fundamental psychotherapy, or in patients who resist subconsciously any suppression of the appetite because of the great pleasure derived from eating, even though they may consciously express a desire to have their appetite curbed. With the administration of amphetamine, reduction in weight may be promptly started, and while this is going on, other forms of treatment may be sought out and administered to aid in giving the patient a sense of well-being. It is this feeling of well-being which reduces the psychic tension and thus combats the increased desire for food. Thus, such forms of therapy as iron in cases of anemia, estrogens for the menopause, androgens or ammonium chloride for premenstrual tension, barbiturate drugs for nervousness and thyroid for those patients with a deficiency of this glandular substance are all most helpful. The results of reduction treatment with the use of amphetamine in combination with other medicaments as indicated are gratifying in a relatively high proportion of cases, excepting those of patients who frequently undergo emotional upsets of such a nature that there may be a return of the original tendency to overeat. Education of patients in this respect is essential, and they should be told that whenever anything occurs which induces in them worry, fear or insecurity they should return to the physician for help. When the patient is relatively unstable and obviously the victim of a severe psychic storm, it is best to have consultation and treatment with a psychiatrist for a more fundamental approach to this problem. Obviously, however, all overweight patients cannot avail themselves of this treatment, and it is up to the physician to carry as much of this load as possible for the patient suitable for mild psychotherapy.

[4] Rosenthal, G., and Solomon, H. A.: Benzedrine Sulfate in Obesity, Endocrinology **26**: 807 (May) 1940. *Myerson, A.: The Rationale* of Amphetamine (Benzedrine) Sulfate Therapy, Am. J. M. Sc. **199**: 729 (May) 1940.

Since amphetamine is of such a vital importance in the treatment of overweight, it is well to consider this drug for its possible harmful effects as well as its beneficial effects. There has been much publicity in the lay magazines in recent years warning the public against the harmful effects of Benzedrine. These harmful effects have been vaguely termed as overstimulation of the heart, addiction and nervous upsets. It is true that a certain type of person with chronic fatigue, who receives significant mental and physical stimulation from this drug, may find a constant need for it and thereby have an addiction to it much the same as that acquired for many other commonly used drugs. Taken properly, however, for the reduction of weight, there is little danger that addiction will occur. There appears to be little or no evidence that amphetamine induces organic damage when given in therapeutic doses. Occasionally one may encounter certain side reactions of little significance, such as dryness of the mouth, a temporary exhilaration with a sense of intoxication which may last only a few days, insomnia if the medicament is taken too late in the day and constipation. The constipation is the most serious of these conditions and may result in part from the reduction diet's low carbohydrate content, which is in itself constipating. Lubrication with liquid petrolatum and the occasional use of a saline laxative may be necessary. Warnings against amphetamine for patients with hypertension have been made by the Council on Pharmacy and Chemistry and the Food and Drug Administration. I have encountered no significant increase in the blood pressure of such patients when the amphetamine is combined with phenobarbital, 15 to 30 mg. three times a day. In 200 cases where the patient had a systolic blood pressure of 150 or more on the first visit, the use of this combination of drugs has in all cases except 4 resulted in a diminution of the blood pressure within one or two weeks. Twenty-eight of 30 persons with hypertensive systolic blood pressure of 200 or more have also responded to the treatment with a gratifying fall in blood pressure within two weeks. This feature is extremely important, because it is the overweight patients with such high blood pressures who are most urgently in need of reduction of weight, and it would be unfortunate if one was deprived of amphetamine for use in such patients for a fear of increasing the hypertension or harming the heart.

One of the most important phases of amphetamine therapy is that it will suppress appetite in practically all cases regardless of the psychic pattern for the overeating tendency, thereby reducing weight promptly and with little effort on the part of the patient in following his reduction diet. This effortlessness in reducing is of tremendous benefit to the morale of patients, since many of them fear their inability to withstand the temptation of food. Not only does the patient lose weight without the need of exerting his so-called "will power," but at the same time there is often an increased sense of well-being and a relaxation of nervous tension; the patient is highly encouraged to continue dieting for prolonged periods of time, unaccompanied by development of symptoms of irritability, weakness and cravings for food which often accompany simple reduction diet therapy. After two or more months the effect of the drug becomes more or less fixed, so that with cessation of therapy the appetite still remains sufficiently suppressed and the diet does not become difficult to follow. This effect is probably due to the spontaneous shrinking of the stomach from partial fillings, and as it shrinks sensations of hunger are of diminished intensity. This state may be maintained for relatively long periods after the cessation of therapy but may be broken by any occurrences which cause pronounced emotional upset or by a change in environment or eating habits. The patient should be cautioned in this regard and educated either to recognize this state of affairs and seek other outlets for his nervous tension or to return to the physician for further supportive treatment during such phases. The majority of patients thus treated obtain satisfactory results, and it is impossible to estimate the benefits to their health, spirits and domestic life which follow this reduction in weight. Those failures which occur are probably in patients whose fundamental psychic pattern is such that more vigorous psychotherapy will be necessary.

Use of thyroid for the reduction of weight is well worth discussing. It is used in tremendous quantities by most physicians who attempt to reduce weight, simply in deference to educational traditions. The rationale of its use is faulty, since few obese patients have a deficiency of thyroid. It is true that many such persons have a low basal metabolic rate, but if the results of the basal metabolic test are recalculated in accordance with the ideal weight of the patient rather than his total weight, it will be found that the metabolic weight is either normal or slightly elevated. The pharmacologic effect of thyroid in stimulating the combustion of fat may be effective, but often the dose approaches toxic levels.[4a] The administration of thyroid to an obese person will result in one of three responses. 1. He may lose weight, but in doing so is subject to a rapid regain because the intake of food has not been controlled adequately. 2. No effect is encountered, although the patient may take huge amounts of the drug. 3. There may actually be an increase in weight due to the development of a stronger appetite through the toxic effects of thyroid, productive of nervousness and irritability. Means [5] has repeatedly deplored the use of thyroid for reduction. In addition there is the possibility of producing significant harm in many persons, especially in the older age group where the cardiac reserve is small. Other possible harm may be in hepatic damage or even bladder disturbances. In this latter regard I have encountered 2 patients on prolonged thyroid therapy who were under the constant attention of urologists for constricted bladder and whose symptoms of frequency and urgency were extreme. The discontinuation of thyroid administration resulted in prompt relief of their symptoms.

[4a] One does encounter a small group of patients who lose weight slowly on an intake of 800 calories a day. Even in the absence of clinical signs of hypothyroidism about one third of these patients lose weight and feel better when they are given 1 or 2 Gm. of thyroid daily, which fact is probably indicative of a masked hypothyroidism.

An essential factor in the treatment of overweight involves proper childhood training. Parents should be subjected to educational campaigns involving the proper feeding of the young, starting with the newborn child. This phase has been described excellently in a recent article by Senn,[6] who amply stresses the various psychic factors in infant nutrition. Bruch [2c] has likewise emphasized these factors and has indicated the harmfulness of treating children as "glandular cases." Pediatricians should be encouraged to place more emphasis on the eating habits of the young from the psychologic point of view as well as from the nutritional aspects, and this should also be placed in the foreground in child welfare clinics and other groups concerned with the proper training of children. Effort expended in this direction will probably be of great value to the future health of the person and prevent numerous ailments which are the result of carrying excessive weight. Probably there will be other benefits, derived as a reflection from this proper childhood training, in regard to such psychosomatic disorders as gastrointestinal, circulatory and dermatologic disturbances.

SUMMARY

Overweight has a strong effect on shortening the life span and increasing the development of degenerative diseases. There is little evidence that obesity is a glandular or metabolic disturbance. The psychologic factors in obesity are paramount, since the tendency to overeat is a strong drive for oral gratification. Any condition which increases the nervous or psychic tension of the person will cause an aggravation of this tendency. These tensions may also result from an organic disturbance. The glandular dysfunctions which contribute to obesity are those which increase psychic tension, namely menopause, puberty, pregnancy and premenstrual tension. Treatment of the patient should be based on an understanding of the psychologic reasons for his overeating. The drug of choice is amphetamine sulfate (Benzedrine sulfate), which is of inestimable value. The possibility of harm from the use of this drug is relatively insignificant. Thyroid therapy in most cases is of little value. The ideal treatment of obesity involves education of the parents to the use of proper eating habits for their children and other psychologic training which induces a satisfactory adjustment to life through emotional maturity.

DECOMPRESSION SICKNESS

Some Factors Which Affect the Incidence of Bends at Altitude

The expression decompression sickness refers to a group of symptoms and signs which occur on exposure of the body to a too rapid and large decrease in barometric pressure and which are most likely due to the formation or growth of bubbles of gas [1] and not initially to anoxia.

The symptoms are essentially the same whether the person is decompressed from high pressure to sea level pressure, as in caisson disease, or from sea level pressure to altitudes of 25,000 feet or above. The treatment of the symptoms is the same whether they occur in divers or in fliers, namely recompression, though, as in caisson disease, the symptoms may occasionally recur or occur after recompression. The prevention of the symptoms is the same in divers and in fliers, namely denitrogenation or the removal of most of the liter of dissolved gaseous nitrogen by the inhalation of pure oxygen for several hours prior to exposure. For these and other reasons it is believed that the cause of the symptoms in the decompression sickness of divers, caisson workers and fliers is the same, namely bubbles, consisting chiefly of nitrogen, which occlude veins, capillaries and, more rarely, arterioles, collect in tissues, especially fatty tissue, and cause pain by distorting nerves or nerve endings.[2]

The most frequent symptoms of decompression sickness are bends, chokes and abdominal gas pains. Bends refers to pain in the region of the joints. Chokes refers to an inability to inspire without coughing, usually associated with a sense of constriction in the chest or throat. The abdominal gas pains are due to the expansion of gas in the stomach and colon and do not occur if the subject can readily expel the gas. Bends are usually associated with collections of gas or bubbles in the veins or in the tissue of the fascial planes about the joints,[2] tension being a factor in their production.[3] Chokes are apparently due to the collection of bubbles in the small branches of the pulmonary artery, and at times some enlargement of the right side of the heart may be detected.[2]

These symptoms may be so severe as to incapacitate aviators during flight. Bends is the symptom which most frequently causes incapacitation. For example, among 852 cases of forced descent from 38,000 feet in an altitude chamber, 73 per cent were due to intolerable

bends, 17 per cent to chokes and bends and 13 per cent to abdominal gas pains.[4]

Since pressurized cabin aircraft were not generally available during the war and since such aircraft are subject to fracture in combat, it was and is of strategic importance to know the factors which may affect the incidence and severity of bends. Accordingly, extensive studies of the subject were made during the war, the results of which will be reported in book form by the Subcommittee on Decompression Sickness of the National Research Council under the editorship of Dr. John Fulton.

Our purpose in this paper is to present a portion of the observations we have made on factors which influence the incidence of bends.

METHOD

The altitude chamber was used exclusively in our study of the factors which affect the incidence of the bends. In our work the temperature of the chamber was controlled at 70 F. and the rate of ascent was 5,000 feet per minute. Young men ranging in age from 20 to 25 years, averaging 23, were used almost exclusively as subjects.

When exercise was performed at altitude, it consisted of three complete squats (heel-sitting position) and five extensions of arms from side to level of shoulder, each hand holding a 4¼ pound (1,928 Gm.) weight.

The exercise was completed in thirty seconds. Control or mock exposures consisted in taking subjects without their knowledge only to an altitude of 20,000 feet, at which altitude bends does not occur.

[4] Gray, J. S.: The Relation of Altitude and Exercise to Decompression Sickness, J. Aviation Med., to be published.

FACTORS

Individual Differences in Susceptibility.—It has been known for almost a century that age is a factor which influences susceptibility to caisson disease.[5] During the recent war it was shown by numerous observers that age predisposes to the symptoms of decompression sickness at altitude.[6]

At the beginning of this war it was assumed that young men in approximately the same age group were either completely susceptible or completely resistant. This view was implied by the assumption that aviators could be classified as regards their susceptibility by one exposure to altitude in an altitude chamber. This assumption was soon found to be false. Its falsity was demonstrated by two types of experiments.

Table 4.—*Selection Obtained by Exposing a Group of 100 Subjects, Noted at 38,000 Feet for Three Hours, Five Times*

The data for the first and fifth flights are shown

Previous Flights, Descents Number	Total		Descents This Flight	
	No	%	No	Rate %
	First Flight			
Total	100	100	30	30 0
	Fifth Flight			
0	40	40	4	10 0
1	29	29	4	13 8
2	15	15	6	40 0
3	11	11	7	63 6
4	5	5	4	80 0
Total	100	100	25	25 0

After the fifth flight 36 had not descended during five flights and 4 had descended during each of the five flights Note that the rate of descent of the 40 who had "passed" four flights was only 10 per cent, whereas the rate of descent of the 100 subjects was 25 per cent.

Table 5.—*Variations Between Individuals in Regard to Tolerance to 38,000 Feet With a Standard Exercise Every Ten Minutes for Two Hours, If Tolerated*

Subjects	No. of Tests	Bends Causing Descents		All Causes of Descents *		Time at Altitude			Total Bends		Descents with No Exercise	
						Exposure						
		No.	% Desc	No.	% Desc	1st Half, Min	2d Half, Min	Average, Min	No.	%	No	%

7	73	68	93	71	96	26	31	28	73	100	..	..

* Bends, chokes, abdominal pain, dizziness (not due to anoxia)
† Change is significant

One way to demonstrate that the susceptibility to decompression sickness varies among young men is to expose a small group of subjects many times under standard conditions. For example, 7 subjects under dietary control were exposed three times a week during the evening to an altitude of 38,000 feet, where they performed our standard exercise every ten minutes for two hours, if possible. It will be noted in table 1 that subject 1, who was the least susceptible to bends, had to descend because of incapacitating bends during 33 per cent of sixty-nine exposures. Subject 7 had to descend during 94 per cent of forty-seven exposures. In addition, the data in table 1 are grouped into periods or groups of exposures to illustrate how the average susceptibility of an individual may appear to vary when the individual is exposed only ten to fourteen times to the same conditions at altitude.

Table 6.—*Effect of a Pecuniary Incentive on the Incidence of Descents Due to Incapacitating Bends*

The subjects were exposed while seated to 40,000 feet for one hour, if possible

	Subjects Not Paid		Subjects Paid	
	No	%	No.	%
Number of subjects exposed	105		50	..
Total bends and chokes	57	54	28	56
Descents due to intolerable bends and chokes	34*	32	10*	20

* This difference could occur by chance in 10 of 100 subjects, 5 of 100 is usually considered significant Descents due to chokes in the nonpaid group amounted to 1 case, and in the paid group to 2

Another way to demonstrate the variation in susceptibility among individuals in the same age group (20 to 25 years) is to expose a large group to the same conditions at altitude a few times. This is illustrated by the data in table 2, 100 young adult males being exposed while seated to 38,000 feet for three hours. It is to be noted that 30 of the 100 descended during the first exposure. After the fifth exposure 36 of the subjects had "passed" five flights and 4 had "failed" the five flights.

Does the susceptibility of an individual change on repeated exposure under controlled conditions? It is necessary to have an answer to this question if a group of subjects are to be exposed repeatedly in order to determine the effect of a factor which may alter susceptibility.

In table 3 data on 7 subjects who were repeatedly exposed under controlled conditions are presented. In the column headed "time at altitude" the average time of each subject at altitude is given for the first and second halves of the exposures. For example, in the case of subject 1 the average time at altitude for the first forty-five exposures was ninety-one minutes and for the last forty-six exposures one hundred and eight minutes. The only difference which is significant occurs in the case of subject 3, who apparently became more susceptible with time. Thus, the susceptibility was significantly changed by repeated exposures in only 1 of 7 subjects. A change in susceptibility with seasons was ruled out in the 6 subjects because these exposures occurred over a period of one year.

Table 7.—*Effect of Exercise on the Incidence of Bends*

	All Types of Bends			Descents Due to Intolerable Bends		
	Total No. of Tests	No. of Cases of Bends	%	Total No. of Tests	No. of Cases of Bends	%
Control diet with exercise	218	181	83	218	151	69
Control diet without exercise	97	61	63	97	35	36

Seven subjects were exposed to 38,000 feet three times a week during the evening and performed the standard exercise given under methods

In regard to the number of descents, 2 subjects in table 1 (subjects 1 and 5) appeared to show some favorable or positive adaptation, but this was not true of the group as a whole. Besides, 2 additional subjects were exposed approximately three times a week to 40,000 feet for fifteen minutes. Subject A developed bends in 23 per cent of the first thirty exposures and in 29 per cent of the next twenty-four exposures. Subject B developed bends in 19 per cent of the first twenty-six exposures and in 17 per cent of the next eighteen exposures.

TABLE 8.—*Rate of Descent on Exposure to 40,000 Feet for One Hour Without Exercise Compared With the Rate of Descent on Exposure to 38,000 Feet for Two Hours With Our Standard Exercise*

	Total Subjects	All Types of Bends		Descents Due to Intolerable Bends	
		No. of Cases of Bends	%	No. of Cases of Bends	%
40,000 ft. seated for 1 hr	101	56	51	33	32
38,000 ft. for 2 hrs. with standard exercise	51	44	86	38	74
38,000 ft for 2 hrs. seated	97	64	66	35	36

Does incentive influence the incidence of descents due to "incapacitating bends"? Incentive is an obvious factor which may influence the decision of a subject to descend when suffering from bends, chokes or abdominal gas.

We attempted to check on the incentive by mock exposures. In another group of experiments we augmented the incentive to remain at altitude by offering a bonus of $0.50 for the first half hour and for every additional fifteen minutes each subject remained at altitude. In the latter experiments the subjects were exposed to an altitude of 40,000 feet while seated. The bonus was offered to a group of 50 subjects and not to a group of 105 subjects.

TABLE 9.—*Incidence of Incapacitating Bends at 38,000 Feet With Exercise (Five Extensions of the Arms with 4¼ Pounds in Each Hand, and Three Complete Squats) Every Ten Minutes With and Without Preoxygenation for One Hour*

Subjects were required to remain at altitude for two hours, if possible

Procedure	No. of Tests	Descents Due to Incapacitating Bends		Average Time at Altitude Out of 120 Min.
		No. of Cases	%	
Control	218	151	69	66
Preoxygenation for 1 hour	50	9*	18	108

* Includes 2 cases of chokes.

TABLE 10.—*The Diet*

Diet	Protein, Gm.	Carbohydrate, Gm.	Fat, Gm.	Calories
Control	79	373	129	2,971
Fat	82	115	252	3,058
Protein	280	130	164	3,116
Carbohydrate	74	574	47	3,015

Referring to table 4, it will be noted that although the pecuniary incentive did not alter the incidence of all degrees of bends and chokes the incidence of descents due to "incapacitating bends" was reduced. The observed reduction in descents, however, could occur by chance in ten of one hundred such experiments; hence, some would not consider this reduction significant.

The results indicate that the incidence of "incapacitating bends" is likely to be lower when the incentive is high, as for example under the conditions of combat.

Exercise at Altitude.—Exercise at altitude definitely increases the incidence of bends and chokes. This was first demonstrated by Ferris and his colleagues.[3]

Our data showing the effect of exercise on the incidence of bends are shown in table 7. In this experiment 7 subjects under dietary control were exposed to 38,000 feet without exercising for a total of 97 subject exposures and with the standard exercise for 218 subject exposures. The exercise increased the incidence of descents from 36 per cent to 69 per cent.

	50 American cheese	100 Eggnog
		50 American cheese

The results recorded in table 8, a large number of subjects being used, show that the mild exercise approximately doubled the incidence of descents. Gray[4] has presented evidence showing that mild exercise decreases the altitude at which descents from bends occur by about 5,000 feet. In his subjects approximately 1 per cent of descents occurred with exercise at 27,000 feet, and 6 per cent without exercise at 33,000 feet.

Preoxygenation or Denitrogenation.—In 1937 Behnke[7] demonstrated that the breathing of oxygen causes gaseous nitrogen to be eliminated from the body and that denitrogenation by this method prevents bends in divers. Soon after the onset of the recent war it was demonstrated by several groups of investigators in Canada and in the United States that denitrogenation prior to ascent would sharply decrease the incidence of bends and chokes.

Our observations on the effect of breathing oxygen for one hour prior to ascent are shown in table 9. The subjects were exposed to an altitude of 38,000 feet and performed the standard exercise. One hour of preoxygenation prior to ascent decreased the incidence of descents from 69 to 18 per cent and increased the average time at altitude from sixty-six minutes to one hundred and eight minutes.

Effect of Diet on Incidence of Decompression Sickness.—This study was undertaken to ascertain whether changes in the diet might account for variations in susceptibility to decompression sickness.

The diets are shown in table 10. It will be noted that levels of protein, fat and carbohydrate in the respective "high" diets are rather extreme. This was considered advisable to exaggerate any effects protein, fat or carbohydrate might have.

The 7 subjects were exposed to 38,000 feet and performed the standard exercise every ten minutes. They remained at altitude for two hours, if possible. The exposures occurred three times a week approximately one and a half hours after the evening meal.

The incidence of incapacitating bends during the three periods on the control diet and the period of the high protein, fat and carbohydrate diets is shown in table 2. It is to be noted that the average descent rate during each of the three periods on the control diet is almost identical. The high protein diet significantly increased and the high carbohydrate diet significantly decreased the incidence of incapacitating bends. The high protein diet decreased the average time of the onset of bends and the average time at altitude. The high carbohydrate diet increased the time of the onset of bends and the average time at altitude. The high fat diet had no significant effect on the incidence of bends.

The results on the effect of the diets on the incidence of chokes and abdominal gas pains are summarized in table 3. The high fat diet appeared to increase the severity of chokes, but this was not significant because of the few cases. The high carbohydrate diet did not increase the incidence of abdominal gas pains. The decrease in abdominal gas pains on the high fat diet is striking. The menus are shown in table 11.

During this study the ground level barometric pressures were recorded. No correlation was found between these records and the occurrence of bends; the same was true of prevailing weather conditions.

COMMENT

These results show that a very high protein diet predisposes to descents due to bends and that a high carbohydrate diet has the opposite influence. Since these effects were observed with extremes in the diet, it is unlikely that ordinary dietary conditions have an appreciable influence on the susceptibility to bends.

Experiments were conducted on the effect of the administration of desiccated thyroid over a period of five weeks. A significant change in susceptibility was not found.

The administration of analgesic drugs and drugs which increase the feeling of well being (aspirin, amphetamine, phenacetin, demerol, codeine) in amounts short of the production of undesirable effects had no significant effect on the descent rate; the average time at altitude, however, was prolonged.

CONCLUSIONS

It seems clear from our observations and from those of others that, with the exception of age, altitude and exercise at altitude are the most important factors which predispose to bends and chokes in aviators. Denitrogenation by breathing undiluted oxygen prior to or during ascent is the most effective method for the prevention of bends and chokes. A high fat diet (250 Gm. daily) was found to be the most effective procedure for reducing abdominal gas pains in our subjects. A very high protein diet predisposes to bends and a very high carbohydrate diet has the opposite effect.

ABSTRACT OF DISCUSSION

DR. A. C. IVY, Chicago: Observations have been made on a number of factors which affect the incidence of bends. Our report emphasizes only some of the factors which we have studied. In the time at our disposal it has not been practical to refer to the work of others in this field. All the work on this subject that has been done during the war will be published in book form by the Subcommittee on Decompression Sickness of the National Research Council under the editorship of Dr. John Fulton.

SURGICAL REFRIGERATION AND PRESERVATION OF TISSUE

LYMAN WEEKS CROSSMAN, M.D., F.I.C.S.
and
FREDERICK M. ALLEN, M.D.
New York

The trial period of surgical refrigeration may be measured from the first publication of experiments on animals and clinical cases in 1937[1] or, better, from the adoption of the method on the surgical service of the City Hospital in 1941.[2] It is now timely to review the experience of these years. The method originated as a shockless anesthesia, but its extension to preservative and other uses has greatly widened its application.

The theoretic or experimental attacks against the principle of reduced temperature were answered in former publications.[3] Opponents attributed to reduced temperature injuries which were actually due to complicating conditions such as pressure or the moisture and other factors which are concerned in "immersion foot"; they also failed to distinguish the different action of cold on the entire body, on local parts of the body or on local parts isolated from the body by amputation or a tourniquet. They also did not differentiate between the effects of cold and the effects of the defen-

sive reactions against cold, which are clearly illustrated by the fatal results of exposure due to exhaustion from shivering and other defenses which prevent fall of temperature until the mechanism breaks down, as contrasted with Temple Fay's artificial inhibition of these defenses permitting temperatures of 10 to 20 degrees below normal to be tolerated safely for as long as a week. Actual freezing, which is instantly fatal for the entire body, can be safely endured for brief periods by local parts, even by such delicate tissues as the liver and the brain. But the "triple response" described by Lewis is the reaction to cold by tissues which retain their circulatory and nervous connections with the body, while a limb isolated by a tourniquet becomes chilled quickly and thoroughly without any such response, and isolated structures such as skin grafts or segments of blood vessels or spermatozoa can be kept alive for days or weeks not only at ordinary ice box temperatures but also when frozen at the temperature of solid carbon dioxide.

PRESERVATION OF DEAD PARTS

As refrigeration is the regular commercial process for preserving dead meat from decomposition, so likewise it can be used to preserve a dead limb which for some reason cannot be amputated but which would set up a rapidly fatal intoxication if allowed to decompose.

For example, in the City Hospital an obese woman aged 67 years underwent operation for removal of an embolus from the common femoral artery. Pulsation returned, but it was absent twenty-four hours later, when another embolectomy restored circulation for four hours. The patient refused any further operation, and in spite of customary treatments the first signs of beginning gangrene were evident the next day, with a faint line of demarcation proximal to the patella. The limb was completely encased in bare ice bags. The appearance of the tissue improved. The line of demarcation was no longer perceptible. In some areas finger pressure caused blanching followed by a return of color, indicating some superficial collateral circulation. After six weeks the woman died of coronary thrombosis, her original ailment having been cardiac. During this time she was comfortable, without pain or toxic symptoms, and the limb was not macerated or malodorous.

A second case was that of a woman seen in consultation in another hospital, who, on account of a simple psychoneurosis, had chronically undernourished herself until her weight was about 80 pounds (36.3 Kg.). There was no known cause, except this malnutrition, for the sudden occurrence of bilateral femoral thrombosis, which necessitated an emergency call for a physician. When the patient was seen in the hospital after the usual measures had failed to restore circulation, there was intractable pain and vomiting, and the prognosis was for less than twenty-four hours of survival. It was advised to surround both legs with ice bags to the groins. Within two hours the pain, which had resisted relief from administration of opiates, was gone, and within six hours liquid nourishment was taken without nausea. The skin, which had been dead white, blue mottled or ecchymotic in different areas, acquired a more normal color. The general nutrition was built up by forced feeding, aided by administration of insulin. After ten days the attending surgeon performed a supracondylar amputation of the left leg, because of gradual return of pain and absence of any signs of circulation below the knee. The arteries at operation were found clotted shut. Healing was delayed by sloughing of some nonviable tissue, but otherwise the collateral circulation sufficed for healing. Pathologic examination of the amputated leg revealed scarcely any perceptible degeneration, testifying to the excellent preservation by cold. The utmost effort was made to save the other leg, in the hope that collateral circulation might with sufficient time make its way below the knee even though the large arteries were obviously blocked. The color of the skin actually became better with time, and sensation, especially of deep pressure, was positive well down the calf. After two weeks a small incision was made in the groin, which proved that the femoral artery was filled with clot to above Poupart's ligament. The artery was not opened, but its nerve plexus was stripped for any possible dilating effect on lower branches. After four weeks of thorough refrigeration, however, the toes and anterior part of the foot became slightly shriveled and wrinkled; sensation was lost in the calf, and pain and discoloration around the knee indicated demarcation. Amputation then in the lower third of the thigh was followed by primary union. Pathologic examination of this leg showed trivial degenerative signs, demonstrating the nearly complete preservation by cold for four weeks. The patient is now walking on artificial limbs.

In other cases the preservation has been effective for variable periods of two weeks and upward. Inevitably, degeneration must occur in a bloodless limb and a modified demarcation must form. The final change in the dead tissues is more in the form of shrinkage and mummification than the usual necrosis. Also pain and a modified intoxication may finally compel amputation. The usual reason for delay in operating is a bad general state of the patient; for example, most of our patients have been those with severe cardiac disease transferred from the medical service because of a major embolism. Besides the chance of constitutional improvement, there is sometimes the advantage of a lower level of amputation, as mentioned hereafter. Obviously, the penetration of cold is more thorough in proportion as circulation is lacking, and efficient preservation even of the deep tissues is thus favored. No tourniquet is needed except briefly for anesthesia at the final amputation.

We consider it clear that the case described by Richards [4] belongs in the category of preservation of dead and already decomposing tissue. The condition was one of embolism and ineffectual embolectomy. The microscopic changes found are sufficiently explained by the interval of several days both before and after the use of refrigeration, and the other evidence now at hand sufficiently excludes refrigeration as a cause.

PRESERVATION OF INFECTED OR INJURED PARTS

The first observations along the line of preservation of infected or injured parts were made when patients entered our hospital with acutely dangerous infected gangrene, but legal permission for the necessary amputation could not be immediately obtained. We thus learned that packing such limbs in ice or ice bags made possible not only a safe postponement of the operation for several days but even an improvement of the general condition so as to lessen the operative risk. This method has been employed by Smith [5] and others without a tourniquet, by Haley [6] with a tourniquet and especially by McElvenny,[7] either by simple chilling or by solid freezing for several weeks. The tissues thus treated, whether living or dead, are sacrificed finally by amputation.

A more definitive preservation may be attemped in treatment of other infections of the limbs, such as gas gangrene. Refrigeration is helpful even when amputation is inevitable, but in less extreme conditions the radical chilling contributes to save the limb in two ways: by directly checking the toxin production and its necrotizing action on the tissues and by gaining time for administration of drugs or other systemic means of cure. A tourniquet is not employed except as a preliminary to amputation.

In cases of severe trauma of limbs, such as described by Mock[8] and by Ottaway and Foote,[9] refrigeration serves preeminently to gain time in an emergency by preserving the injured part for days or weeks until the patient gains sufficient constitutional strength to withstand amputation. A secondary benefit, however, is reported as the development of collateral circulation during the time thus gained, so as to permit a lower level of amputation. This may make the difference between an emergency amputation high in the thigh and an amputation just above the knee a few weeks later. While this difference has practical importance for the patient's subsequent walking and earning ability, it also carries the theoretic lesson that prolonged refrigeration does not prevent collateral circulation by vasoconstriction. On the contrary, we have suggested that it may prove to be the best treatment for traumatic arterial spasm, but we have not yet had any cases for demonstrating this theory.

The importance of this preservation of tissue is illustrated also in cases in which it is not used. In France a war correspondent's jeep was crushed by a tank, and the man died the next morning in a hospital during attempted amputation of one leg.[10] In a marine with a thigh shattered by shell fragments signs of gas gangrene developed during 18 hours in a hospital; amputation was then performed, and he died twenty hours later.[11] Such accidents occur by thousands in war and in peace, and undoubtedly many losses of life or limb could have been prevented by adoption of this method of preservation. We have not yet had opportunity to test the proposal of refrigeration to extend the time limits and improve the results of embolectomy in reasonably early cases. Surgeons having experience with any of this wide range of accidents can render service by publishing their results to stimulate wider use of the plan.

PRESERVATION FOR RECONSTRUCTION

A still higher accomplishment is when refrigeration not merely tides over an emergency but prevents amputation altogether. A personal communication from Dr. I. W. Nachlas, of Baltimore, may be quoted as a perfect example.

> The patient who comes to us in shock from multiple injuries and presents severe damage to his extremities offers a real problem. Though treatment for shock is instituted immediately, the traumatized extremities must be handled promptly so as to avoid infection and, in addition, to eliminate a contributing factor to systemic shock. This leads in many instances to amputation, usually the guillotine type, an operation which in the hands of trained surgeons is said to produce a minimum of shock. If the same patient were to come in without restrictions against reconstructive surgery, his extremities might be subjected to reconstruction rather than amputation. Obviously a procedure that will permit a delay in the operative work without endangering the patient from either local infection and decomposition or addition to the shock should prove of great value.
>
> We have met such situations by a device that has proved eminently satisfactory. The following case is an illustration in point.
>
> A man was brought in for injuries sustained in a blast accident. He was in shock and gave evidence of grave intra-abdominal trauma, as indicated by blood in the stool and urine. His abdomen was rigid. In addition, one hand was amputated by the accident at the level of the wrist, and the skin of the forearm was shredded for about 2 inches (5 cm.) proximally. The other hand was a mass of mangled tissue, and we were asked to amputate this extremity in the forearm. Instead of an emergency operation being done on these extremities, both limbs, which had been amply powdered with sulfanilamide, were refrigerated by having them surrounded with crushed ice. Plasma and transfusions were used freely, but it was almost two and a half weeks before the abdominal symptoms cleared up enough to permit us to do reconstructive work on the upper limbs. At that time, definite amputation was done on the one that had already lost the hand, the level being only 1 inch (2.5 cm.) above the lacerated skin area. This healed per primam in the usual length of time. For the other hand skeletal traction was used, the fingers being extended on a banjo splint. A minimal débridement was performed. The compounded fractures were covered with sulfanilamide powder, and the entire palm, which had been denuded of skin by the injury, was covered with sulfanilamide ointment.
>
> The clinical course has been simply phenomenal. The multiple fractures of the hand have all healed in good position with the exception of the little finger, where the compound fracture of one of the phalanges has undergone some sequestration from osteomyelitis. Granulations have filled in the large gaping areas, and epithelium has covered a large proportion of the exposed areas. At the present time a relatively small spot remains to be covered by a graft. The function of the thumb and the adjacent three fingers has already been restored. The little finger is still immobilized. Under conventional treatment or at the front, this patient would have come out—if he had come out—without the two forearms. He now has one useful, well functioning hand to save him from the horrors of no prehensile limb.

The minimal débridement is one noteworthy point in this case. As mentioned in our former papers, we do not débride for either mechanical wounds or burns. Refrigeration permits saving the whole of the living tissue, which is partly sacrificed by the usual débridement.

PRESERVATION OF SEVERED PARTS

Mass and complexity of structure evidently are factors in the capacity for preservation, because there is no known way of preserving limbs in a chilled or frozen state for weeks or months, as is possible with some isolated tissues or grafts. The reduction or near suspension of metabolism by cold can, however, enable limbs to survive without blood supply for a surgically important period.

An illustration in minor surgery was reported by one of us,[12] showing that refrigeration aids in restoring fingers which have been cut off so as to hang by a mere shred of skin. Such a finger may be kept well chilled according to instructions given by telephone and will thus remain viable at least during several hours which may elapse before the patient can reach the doctor. Theoretically the interval might extend to twenty-gangrene. Refrigeration is helpful even when amputation is inevitable, but in less extreme conditions the radical chilling contributes to save the limb in two ways: by directly checking the toxin production and its necrotizing action on the tissues and by gaining time for administration of drugs or other systemic means of cure. A tourniquet is not employed except as a preliminary to amputation.

>
> The clinical course has been simply phenomenal. The multiple fractures of the hand have all healed in good position with the exception of the little finger, where the compound fracture of one of the phalanges has undergone some sequestration from osteomyelitis. Granulations have filled in the large gaping areas, and epithelium has covered a large proportion of the exposed areas. At the present time a relatively small spot remains to be covered by a graft. The function of the thumb and the adjacent three fingers has already been restored. The little finger is still immobilized. Under conventional treatment or at the front, this patient would have come out—if he had come out—without the two forearms. He now has one useful, well functioning hand to save him from the horrors of no prehensile limb.

The minimal débridement is one noteworthy point in this case. As mentioned in our former papers, we do not débride for either mechanical wounds or burns. Refrigeration permits saving the whole of the living tissue, which is partly sacrificed by the usual débridement.

PRESERVATION OF SEVERED PARTS

Mass and complexity of structure evidently are factors in the capacity for preservation, because there is no known way of preserving limbs in a chilled or frozen state for weeks or months, as is possible with some isolated tissues or grafts. The reduction or near suspension of metabolism by cold can, however, enable limbs to survive without blood supply for a surgically important period.

An illustration in minor surgery was reported by one of us,[12] showing that refrigeration aids in restoring fingers which have been cut off so as to hang by a mere shred of skin. Such a finger may be kept well chilled according to instructions given by telephone and will thus remain viable at least during several hours which may elapse before the patient can reach the doctor. Theoretically the interval might extend to twenty-hydrochloride will be necessary when the deep nerves are reached. One of us (L. W. C.) was thus able to cut through the layers of a thick abdomen down to the peritoneum, which proved sensitive. Partial anesthesia for a hip joint operation was mentioned previously.[3]

The dwindling attacks against refrigeration can now be answered in two ways.

First, mortality figures are not a sole criterion of surgical skill. Surgeons of unquestioned standing have reported high mortality rates in series of amputations, and many of them have testified that the number of these deaths has been reduced by refrigeration. Phenomenally low mortality rates furnish no evidence that any surgeon dealing with such favorable material could manage the worst cases of a large public hospital with equal success or without the need for refrigeration. As we have mentioned elsewhere, our mortality rate from only one complication, namely, heart disease, during the several weeks following amputation is greater than the total mortality rate of these critics. Also the lowest mortality rate is too high if it can be reduced, and there is reason to believe that refrigeration used in the few desperate cases in these select series would save some lives, just as it has in the experience of other surgeons.

Second, we may revert to the stated facts, e. g., that animals' legs have survived application of a tourniquet and refrigeration for fifty-four hours, that vascular anastomosis and replacement of dogs' legs have succeeded after amputation and refrigeration for twenty-four hours, that human amputation wounds have healed in areas that had been iced for from two to four weeks and that a mangled hand can be reconstructed after refrigeration for two weeks. These facts, verified from many sources, permit judgment of assertions made without any proof (e. g., by Standard[16]) that two or three hours of refrigeration anesthesia gravely injures tissues and also makes them unfit for the delicate hemostasis which distinguishes his amputations. All such statements imply that the method has not been learned and that perhaps freezing has occurred, since all surgeons who have used the method correctly can corroborate the proofs that the cold tissues are absolutely unchanged in consistency and are fit for the most painstaking surgical procedures. Also one of us (F. M. A.), in many years of experience, has never encountered a surgeon who did not reject some patients with gangrene as inoperable, until with the advent of refrigeration we have operated on every patient regardless of condition; some statistics may thus be explained.

FURTHER DEVELOPMENTS

Cold has the unique ability to inhibit simultaneously pain, shock, infection, toxic absorption and tissue devitalization. Speaking always of emergency treatments at temperatures above freezing, we can state the general rule that the lower the temperature, the greater is the effect. Among the results of our recent experiments on animals[17] are the three following effects:

1. *Shock.*—While all writers now agree on the value of reduced temperature in shock, the prophylactic effect is still greater than the therapeutic effect. Fay[18] first introduced systemic hypothermia in shock treatment, but there is no record of his having used it prophylactically in operations. Our experiments show that while body temperatures of 80 F. or lower are not so powerful as the near-freezing temperature of local refrigeration the inhibition of shock is nevertheless striking. This fact may have occasional surgical application; for example, in the case of a desperately injured patient requiring a double hip disarticulation which would ordinarily be fatal. The recommended procedure then would be to apply ice to the hip region for the utmost local penetration and, at the same time, with the patient under sedation allow the general body temperature to fall to about 80 F. In this way the operation can be performed with remarkably little shock and also with minimal need for anesthesia.

2. *Abdominal Operations and Injuries.*—Preservation of tissues by reduced temperature is universal throughout the body, but the inhibition of shock is not universal. Reduced temperature is found to be not helpful, in the sense of either prophylaxis or therapy, for shock from intestinal trauma, and therefore the aforementioned systemic hypothermia cannot be recommended for abdominal operations. This new differentiation between forms of shock may have wider theoretic significance.

3. *Burns.*—The superficial location of burns makes them accessible to temperature treatment, and they preeminently need the combined inhibition of pain, shock, infection, toxic absorption and tissue devitalization. The usual inertia of authorities has delayed the adoption of this treatment for several years, but any intelligent trial of local refrigeration will prove its dramatic benefits. The possibilities of systemic hypothermia for the most extensive burns will be discussed elsewhere.

CONCLUSIONS

1. Experience to date continues to confirm the safety and benefit of refrigeration anesthesia.

2. Not only is this anesthesia by brief chilling advantageous for orthopedic and reconstructive operations, but also successful healing has been reported in limbs which have been refrigerated for a number of days or weeks. Besides clinching the harmlessness of the low temperature, these observations point the way to new developments in surgery.

3. Recent experiments define some limitations and also extensions of hypothermic treatment. They suggest uses of reduced temperature prophylactically in some operations involving shock and therapeutically, especially for burns.

ABSTRACT OF DISCUSSION

Dr. Bruce M. Anderson, Oakland, Calif.: There is no doubt of the value of this procedure. I want to offer one note of caution from what I have observed in the practice in Oakland, i. e., that care should be taken in the giving of anesthesia, that the complete equipment is available and that well trained personnel are on hand, so that one does not run into a difficulty which has been experienced over there in a couple of instances, in which the anesthesia has been carried to such an extent that the operation was impossible; it was like operating on a block of ice. One thing of real interest which has occurred to me as a possible explanation is the fundamental physiology of the anesthesia which is produced. One of the men from Stanford University who has been much interested in this field of physiology can give us a more complete explanation, so I should like to give four hours or more, though there is no clinical proof of such a maximum. After the finger is sutured in place the reduced temperature is still continued for several days but is raised slightly day by day as the nutrition of the severed part improves.

The experimental restoration of entire limbs was demonstrated by Blakemore and co-workers,[13] who cut off dogs' legs, kept them in a refrigerator for twenty-four hours and then replaced them, with successful healing. Since animals' legs have survived after having been deprived of circulation by a tourniquet for fifty-four hours and tails similarly for ninety-six hours, the feasible limits of preservation of severed limbs may well exceed twenty-four hours. If a limb is fairly cleanly amputated, for example in a sawmill accident, there is a challenge to any nearby physician to pack such a part in ice and send it along with the patient to a hospital equipped for the necessary anastomosis. In this airplane age it is surprising that no attempts of this kind have yet been reported. A commoner type of case is the wounding of limbs in various ways which sever the main blood vessels but leave other connections with the body. Amputation is the established routine, but it is entirely practicable for such a patient to be transported long distances with the damaged part surrounded with ice or ice bags, and considerable gaps in the blood vessels can be bridged by the recent methods of anastomosis. Nothing is risked or lost, and even if there is failure in a majority of cases a minority of successes will justify the attempt.

ORTHOPEDIC OPERATIONS UNDER REFRIGERATION ANESTHESIA

Case 1.—A man fell in the street, sustaining a compound fracture dislocation of one ankle. He was treated elsewhere, and one month after the accident he was admitted on the service of Dr. Charles Murray Gratz in City Hospital. Examination showed a compound fracture dislocation of the right tibioastragalar joint, with osteomyelitis, and a complete tear of the internal lateral ligament. In an operation with the part under refrigeration with a tourniquet, continuous traction was put on the misplaced foot; scar tissue of the inner mortis of the ankle was left intact but the periosteum on either side retracted; the fibrous tissue of the inferior portion of the ankle was carefully dissected and the entire dislocation placed in extreme abduction. A Lane bone skid being used the reduction was accomplished without difficulty. With plastic reconstruction of the lower end of the tibia, the upper portion of the astragalus was made into a "V" to fit the mortis in the tibia. Two wires were then used to hold the desired position. A catheter was placed in the bottom of the wound, covered by a penicillin dressing, and the wound was packed with petrolatum and closed with two retention sutures. A cast was applied from the toes to midthigh.

There was no pain or discomfort in the operation; the relaxation of the parts was complete, and when the tourniquet was removed the circulation of the foot returned promptly. The subsequent recovery was uneventful, without sign of harm from the low temperature or the tourniquet.

Case 2.—A 44 year old man fell, fracturing the right femur at the site of chronic osteomyelitis of twenty years' duration. He was treated elsewhere and was admitted to Dr. Gratz's service nine months after the accident. Roentgenograms showed transverse and comminuted fractures with decided angulation and a Lane plate separated from the fragments, three screws still in the plate and two screws in the soft tissues. The plate and screws were removed and the fragments routinely treated. Four months later, with the part under refrigeration anesthesia, a 35 cm. intramedullary nail was introduced, which held the fragments in correct alinement. Roentgenograms taken five months later showed good position and moderate callus. There was a shortening of 3 inches (7.6 cm.).

INCIDENTAL DEDUCTIONS

Our former papers have mentioned that the customary treatment for hemorrhage in a limb, namely, application of a tourniquet and release of it about every half-hour, is by no means harmless to tissues, especially if they are wounded or potentially infected. Refrigeration permits application of a tourniquet for much longer periods and with much less harm. It is becoming accepted that every asphyxiated limb should be kept at the lowest possible temperature short of freezing. If actual refrigeration is not available, any other means of cooling, by air current, water, alcohol and similar means, are helpful in proportion to the degree of reduction of temperature.

We have also mentioned previously the absence of any clinical signs of harm from either the cold or the tourniquet in our operations and also that repeated microscopic studies of the amputated limbs have shown no detectable alterations of any tissues from skin to bone marrow. Such specimens, however, show only the conditions during the chilling, not the after-effects; also they do not include the tourniquet zone, where the direct pressure is likely to produce the maximum injury, especially on blood vessels and nerves. To cover this point the following clinical experiment was performed in cooperation with Dr. J. R. Lisa, the hospital pathologist. In a patient scheduled for an amputation low in the thigh, a tourniquet was applied distal to the proposed incision in the skin, and the limb was thus refrigerated for twenty-four hours. A tourniquet was then placed on the upper thigh, with the usual three hours of refrigeration for anesthesia. The first tourniquet was left in place, making twenty-seven hours of tourniquet pressure with ice pack. Examination of the amputated limb then revealed no detectable microscopic changes in this zone of twenty-seven hour pressure or proximal or distal to it. We therefore see no reason to fear this pressure for the usual period of three hours or less.

For anybody who still has fears, compromise methods are available. If there is fear not of cold but of the tourniquet, there is the possibility of good anesthesia without a tourniquet,[14] provided the blood flow is scanty on account of arteriosclerosis or other lesions. If the long application of the tourniquet invites criticism, there is the previously demonstrated possibility [3] of changing the position of the tourniquet every hour or half-hour, with an interval of five or ten minutes of free circulation each time. If the refrigeration is continuous this plan makes only a slight delay in obtaining satisfactory anesthesia, even in limbs with a normal supply of blood. If there is fear of the prolonged low temperature, it has been found [15] that fair anesthesia is provided by temperatures as high as 60 F. Therefore the time of refrigeration of a limb can be shortened, or prolonged cold can be applied on deep locations, such as the hips or trunk, where use of a tourniquet is impossible, with the understanding that some infiltration of procaine hydrochloride will be necessary when the deep nerves are reached. One of us (L. W. C.) was thus able to cut through the layers of a thick abdomen down to the peritoneum, which proved sensitive. Partial anesthesia for a hip joint operation was mentioned previously.[3]

[18] Fay, T.: Pennsylvania M. J. **46**: 332-333, 1943

Professor John Field, Stanford University, Calif.: It is amazing how much cold mammalian tissues will stand after isolation and under the experimental conditions which make the supply of oxygen and the removal of carbon dioxide easy. Slices of the cerebral cortex of a rat may be maintained at a temperature of about 0.1 or 0.2 C. for as long as an hour. On rewarming they will recover completely their capacity for oxygen consumption and for glycolytic reaction. We do not know whether other functional activities would be restored, but insofar as the metabolic picture is concerned a complete restoration of the capacity for glycolytic reaction and capacity for oxygen consumption occurs after as long as an hour at more than 0.1 C. This is a far lower temperature than the rat can stand. The intact animal dies at 10 or 11 or 12 C. body temperature, because of the failure of the great supply systems, the circulation and the respiration. If by means of what amounts to artificial circulation and respiration in this particular type of study one maintains a suitable supply of oxygen, the tissues can stand a good deal more lowering of temperature, and this leads to a speculation that has been of interest to me. If tissues, even mammalian tissues, can stand such little temperatures as this, what can be thought of as constituting life? If it is taken to extremes, certain protozoa and certain bacteria have survived temperatures as low as the temperature of liquid helium, —272, and it is not an overstatement to say that little is going on chemically at such temperatures as this; yet under these conditions these cells survive for a more or less indefinite time. It looks as though life fundamentally is a sort of molecular pattern. It does not depend on continuance of chemical reaction, certainly not at great speed, but if the temperature is such that the compounds present in the cell—proteins, carbohydrates, fats and other materials—are all the time breaking down, so that the metabolism is going on at the higher levels of temperature, then the reactions are essential. So the survival of the cell at —272 merely implies that the reactions which take place are not always recoverable. It is a rather striking point and one which serves to emphasize the fact that harm done to a cell by interference with the energy-building reactions, oxidation and fermentation does not occur if at the same time the over-all chemical metabolic picture is also reduced, that is, if the temperature is dropped so that these reactions will go down together. This affords a rather strong rationale for the use of refrigeration anesthesia and chilling processes for the preservation of tissue. Again we have this overall reduction on the application of cold in contrast to a probably somewhat distorted metabolism of the cell as a result of interfering with metabolic processes by means of this or that pharmacologic lesion.

Dr. Stephen Holstein, New York: During the war, while I was in the Pacific, I saw a patient who presented a rare syndrome, only 2 cases of which have been reported. There was paralysis of the anterior group of muscles of the leg, secondary to an acute spasm of the anterior tibial artery. A sympathetic block was done in an attempt to restore vasodilatation, but apparently in an area of reduced supply of oxygen the smooth muscle of a vessel wall remains in spasm under reduced oxygen content, because its requirement is less than that of the surrounding tissue. This young man went down hill. A biopsy specimen of the lower portion of the anterior tibial muscle was taken and on microscopic section it was found that the striations had disappeared but the nuclei remained in place. The part was refrigerated all the way up to the hip for one week, and there was progressive increase in the amount of destruction, so that the next step my associate and I were forced to enter on was a complete block resection of the anterior tibial muscle group. We had originally planned to go into the area with the idea of removing the entire section of the artery involved, in the hope that with the removal of an artery in spasm the remainder of the arteries might relax sufficiently in order to produce some circulation under decreased temperature of refrigeration to save this man's leg. After getting in there, we realized that the entire muscle group was now completely degenerated and that section of the artery itself would not be sufficient, so we removed the entire area. I want to ask why the failure of reduced oxygen consumption occurred in the presence of this icing that we administered? Is it possible that icing in a diseased state of a vessel will be of no avail, or do you think that we can still hold out hope for a condition of this sort, of acute arterial spasm, using refrigeration with the hope that by gradual defrosting the limb can be saved? The most rapidly degenerating part occurred during the defrosting stage. His condition was much worse than it had been prior to the administration of any ice at all.

Dr. H. H. Stryker, Kalamazoo, Mich.: It occurred to me during the war that the operating time and the shock to the patient might be cut down by taking the graft ahead of time. My colleagues and I did this in 6 cases under refrigeration anesthesia, taking a tibial graft. Technically, it is nice; it gets away from the uncomfortable position of the patient necessary if taken at the time of spinal fusion. However, we did get some weakness in these legs afterwards. Most of this was temporary and cleared up rapidly, but in 2 cases the patients had a foot drop, which persisted for an uncomfortable period but eventually cleared up. Up to this time, which is about a year and a half or two years since the last was done, there have been no residual paralyses. I am not sure of the cause of the paralysis and the weakness, whether it is due to the cold or due to the application of the tourniquet at the time of refrigeration. Since only the anterior groups seemed to be involved, I think that perhaps it was due to the pressure of the peroneal nerve just above the knee, where the tourniquet was applied. I do not know whether any one else has had this experience. Perhaps with a different type of tourniquet, with the air pressure varied or better controlled, this might be a better type to use to avoid this paralysis. We used an ordinary flat rubber tourniquet about 1½ inches (3.7 cm.) wide about three turns around, using it a good deal as in cases of amputation.

Dr. Lyman Weeks Crossman, New York: I am interested in Dr. Anderson's remarks about the block of ice, because McElvaney uses the block of ice definitely. If there is an extensive infection and he thinks that the patient's condition is such that there must be an amputation but the patient's general condition will not permit any sort of operative procedure, he actually will freeze the part so hard that it feels as though it were marble. He says that he feels as though he could chip it with a chisel. In other words, he does a physiologic amputation by means of the block of ice. We advocate 40 degrees, which is 8 degrees above freezing. A near-freezing temperature might produce a frostbite, and primary healing is not possible after frostbite. Some doctors report that they do not get primary healing. This may be due to the choice of level for the amputation—where there is insufficient circulation for healing or the temperature of the part has been too low, possibly where there is a breach in surgical technic or where infection is present in the stump at the time of operation. I was much interested in Professor Field's talk on physiology. We know that the metabolism of the part is reduced tremendously, and we count on that, because as long as we can keep the metabolism at its low ebb, with the cells in a state of suspended animation, we know that the patient will not suffer from that part. There can be no shock, and there can be no spread of infection or absorption of toxic material. If we keep the temperature at 40 F. the patient will have no pain. When there is no pain the temperature is elevated. Usually at 60 or 65 F. there is a return of definite metabolic processes which will permit healing. Originally we removed the sutures on the seventh day, but on the eighth day there was a gaping of the edges of the skin. We realized that the low temperature had reduced the metabolism and healing power, and the part could not heal in seven days. Now sutures are removed on the twelfth or fourteenth day, and there is firm healing. In Dr. Holstein's case the pathology was probably present in the artery and the damage was complete before the refrigeration began.

Special Article

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(*Continued from page 318*)

(Note.—*Following is the fourteenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of The Journal. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in The Journal. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—Ed.)

CHAPTER 14. *Confusion and Strife*

1890-1894

1890

NASHVILLE

The bound volume of The Journal for the period January to June 1890 contains a list of editorial writers; these no doubt contributed some of the scientific editorials as well as those having to do with the work of the organization.

S. T. Armstrong, U. S. Marine-Hospital Service.
Robert H. Babcock, Chicago.
Henry T. Byford, Chicago.
Archibald Church, Chicago.
J. C. Culbertson, Cincinnati.
Nathan S. Davis, Chicago.
Richard J. Dunglison, Philadelphia.
James M. French, Cincinnati.
Albert L. Gihon, medical director, U. S. Navy.
Junius C. Hoag, Chicago.
John H. Hollister, Chicago.
Bayard Holmes, Chicago.
W. W. Jaggard, Chicago.
Samuel J. Jones, Chicago.
Charles Lodor, Chicago.
Franklin H. Martin, Chicago.
L. L. McArthur, Chicago.
Harold N. Moyer, Chicago.
Wolfred Nelson, New York.
John Shrady, New York.
William L. Worcester, Little Rock, Ark.
Richard M. Wyckoff, Brooklyn.

Here are such distinguished names in the history of the Association as J. C. Culbertson, John H. Hollister and N. S. Davis, all of whom served as editors of The Journal. They aided with the editorials on the work of the Association.

The Journal for May 3, 1890 contains a review by James E. Pilcher, assistant surgeon in the United States Army, of "The Annals and Achievements of American Surgery." The review is especially important because it established the place that American surgery was to occupy in the development of surgery throughout the world. Pilcher gives credit to Dr. Philip Syng Physick of Philadelphia for the foundation of American surgery, calling him the father of American surgery. Then came the famous Valentine Mott of New York, whose name is still preserved in the annals of the great metropolis. Indeed, there is a special society dedicated to his memory. Pilcher recorded the great achievements of surgery in the history of American medicine; his review must have taken many hours of research into medical literature. He concludes concerning the American surgeon that "his brilliancy and force as a teacher, his originality and skill as an operator, and his grace and impressiveness as an author have united to secure the high position accorded to him by other nations." The history of the growth of medicine in our modern times reveals the rise of American surgery to great eminence, to leadership throughout the world. But some of the greatest names of those who built American surgery had not yet begun to appear in the Transactions of the American Medical Association!

With May The Journal of the American Medical Association issued the special edition which had now become a feature in American medical publishing. This issue, which forecast the program of the convention, was placed in the hands of every regular registered physician in North America. It was made the occasion of still further promotion of The Journal to the medical profession. The editors took great pride in pointing out that the weight of the paper of the special issue amounted to fifteen and a half tons.

The Rush monument was still not doing well; the collection had just barely gone beyond $1,500, and it seemed that the minimum cost would be not less than $15,000.

PLANS FOR THE CHICAGO WORLD'S FAIR

At this time The Journal was agreeably surprised to read in the *Cincinnati Lancet Clinic* that a world's fair was to be held in Chicago in 1893 and that it might be a good idea if the American Medical Association, which had always "made Chicago its center," took the leadership in planning an exhibit for demonstration to the public of the great advances that medical science had made during the years. This occasion might serve "to bring into closer relations with us the medical fraternity of Central and South America."

THE NASHVILLE MEETING

The meeting convened in Nashville, Tenn., near the end of May. The President's address, which had been printed in the issue published during the week of the annual session, was a review of the relations of medicine to public health. The President recognized the desirability of representation by the public on state boards of health and he urged strongly a wider extension of public health activities.

There had been much gossip in various portions of the country during the year on the necessity for reorganization of the American Medical Association.

The committee on the Rush monument suggested that failure of the appeal to the general medical profession should probably yield to a specific appeal to a few leading members. If this appeal failed, it would probably be better to determine "whether the memorial shall be the imposing one your committee have in view, or such humbler testimonial as the money they then have in hand shall justify them in obtaining."

The Board of Trustees reported that The Journal had been under the direction of the committee on management. It now had a weekly circulation of 5,100 copies, with its own printing office. An editor had not been named, but one of the members of the committee on [illegible]ently Dr. John H. Hollister of [illegible] had been filling this function. A resolution came from Ohio for the appointment of a special committee of one from each state to consider The Journal and to see what could be done to superintend its editorial management and to widen its circulation. This resolution was laid on the table, but it was an indication of *underlying dissatisfactions* which were to come to a focus later in the year.

There were other political dissatisfactions which became manifest. A resolution was offered to the effect that "at future meetings of this Association, the business of the general sessions shall be conducted from the floor of the house, and no one occupying a seat on the platform shall be recognized by the President, excepting the secretary." This resolution was adopted.

An attempt was made to pass a resolution making every medical society with a membership of more than a hundred a branch of the American Medical Association, but the resolution failed.

CHICAGO OR WASHINGTON

The Journal began to reflect increasingly in its editorials its feeling of unrest. The New York State Medical Society had reorganized under a representative system in which the various divisions of the state society were directly related to the society itself. Now for the first time appeared the suggestion that "our *local societies could be represented by delegates in the* state societies, and these, in like manner, in the national Association."

Suddenly in December an announcement appeared in The Journal to the effect that the Board of Trustees had held a special session in Washington, D. C., to consider whether or not The Journal should be moved to Washington. Six of the Trustees were present. The first point raised was that Dr. John H. Hollister, while [illegible]ing as supervising editor, had been receiving $250 a month, a fact which did not appear anywhere in the minutes of the organization. The secretary pointed out that he had no record of any meeting of the board at which such an action was taken. The chairman of the committee on management stated that no meeting of his committee had been held. At the afternoon session Dr. I. N. Love, chairman of the board, recommended removal of The Journal to Washington. There was much discussion, and it was decided to put the matter before the members of the Association. Finally a group were constituted a committee to prepare a resolution, which read:

> *Resolved*, That the sense of the Committee be that the home of The Journal of the Association should be permanently at Washington, D. C.
>
> *Resolved*, That the Trustees incorporate the foregoing resolution in their report to be presented at the next meeting of the Association.

A resolution was then offered by John V. Shoemaker that the Trustees "recommend the members of the Association, or the various state and local medical societies in affiliation with the Association, to contribute or subscribe funds for the erection of a permanent building as a place of meeting as well as a library and office for the American Medical Association."

The Trustees recommended that these resolutions be printed in The Journal and that members be given opportunity to discuss the subject, with, however, a limitation of individual letters to fifteen lines. Then Dr. Hollister was instructed to make such contracts as might be necessary for the continuation of The Journal until the next meeting of the Association, and the Board of Trustees went off to pay a visit to the President of the United States.

1891

WASHINGTON, D. C.

Something happened by the time the next volume of The Journal was published; it bears on its title page the name of J. C. Culbertson as editor and the announcement, a little further along, that J. C. Culbertson is editor and manager.

In the first number for the year the correspondence began with a highly amusing combination of three letters, the first of which, from a doctor in Texas, suggested that The Journal remain in Chicago; the second, from a doctor in Tennessee, that it be moved to Louisville, and the third, from a doctor in Iowa, who wondered what "occult reason or grounds" demanded removal of The Journal since the objections to its removal were so strong.

The Journal began begging for more contributors to this debate, because it was apparently of little interest to the medical profession as a whole. By the middle of January there were seven letters—six for Chicago and one for Washington—and in the next issue nine letters (all for Chicago) and one indicating that apparently a little faction was having a whim in the matter that should not too greatly disturb the majority. The last issue for January turned up with three pages of letters, including among the contributors such distinguished names as William T. Corlett of Cleveland, who simply said "I prefer Chicago," and Henry O. Marcy of Boston, who had about 1,000 words on the subject. Marcy went directly to the point. He felt that the agitation for removal was simply that of one trustee who voted for it because he was pledged to that course of action before his appointment. "Why," said Dr. Marcy, "this agitation for Washington? Is it because Washington is the capital city and the center of the political influences of our country? Some have felt that already the greatest danger to our Association and its journal lies in the fact that a political element has entered into its organization and is seeking control. If there is reason for apprehension in this direction, it would be a strong argument for its removal *from* Washington had it been established there instead of at Chicago."

Dr. Solomon Solis-Cohen of Philadelphia contributed 1,000 words in which he said that The Journal had not been well edited, that there would be less tendency in Washington to debase The Journal into a local organ, that America must have a scientific center and that there could only be one center and that was Washington. He argued that any defects in The Journal were not those of the editors, since they were all first class scientists and that therefore they must be due to the location.

The battle waged through issue after issue, seldom with less than ten letters in each number of The Journal. Dr. Harold N. Moyer of Chicago made it his special task to answer Dr. Solomon Solis-Cohen. He pointed out that if there was any peculiar miasm around Chicago it probably prevailed equally around Philadelphia, New York, Boston and Baltimore. He congratulated the profession of Washington on being free from this kind of infection. He wrote sarcastically: "As near as we can analyze Dr. Cohen's statement, there seems to be in Washington a great, intangible, psychic entity that has its being as an incorporeal body working in and for the good of the but not of it, for they are of the earth, and this is of the spiritual and invisible." And very succinctly Dr. Moyer pointed out that if there was anything to be done about improving The Journal it would have to be done through brains and not through transferring the "editing, printing, press-work or binding to either Washington, Oshkosh or Kalamazoo."

The letter of Dr. Solomon Solis-Cohen served to focus the attack on him and to arouse to the defense of Chicago so many that he well nigh defeated the cause by his advocacy of it. On another occasion a similar bitter attack was to gain him overwhelming support. But this time it concerned his attack on proprietary medicine.

By the end of February medical societies were beginning to take action; first was the Chicago Medical Society, which opposed the removal vigorously. A long letter from Charles A. Hough of Ohio began with the statement that Washington had never produced a medical journal, national either in character or in reputation, and that was the very reason "why she is just the place which *can* do it." They then poured satire on the proponents of the removal to Washington and particularly on Dr. Solomon Solis-Cohen. The correspondence is typical of the personal journalism of that period. Dr. Hough feared that there might be infection of the new magazine by the pathogenic germ of the Congressional *Globe*.

A New York physician, Dr. Thomas H. Manley, said that it was for The Journal to lay plainly on the table the reasons underlying the demand for removal, for "it may as well be generally known that this transference of location cannot be consummated *except through specious, delusive argument, wily manipulating and shrewd diplomacy, with the aid of sharp parliamentary tactics.*"

The letters continued issue after issue, the vast majority of them opposing any removal to Washington and many beginning to inquire more and more into the motives. More societies began introducing resolutions. The presidents of state medical societies began recording themselves in behalf of maintaining the headquarters office in Chicago. Then the suggestion began to be made that the whole question be referred back to the Board of Trustees. Many an important leader in medicine contributed his personal sentiments to the controversy. A leader in American medicine of that day, Dr. Cornelius G. Comegys of Cincinnati, wrote a most enlightening communication of several thousand words in which he made it clear that The Journal would have to have a full time editor. He pointed out some other objectives, one of them a full time secretary of public health in the President's cabinet. To him the *British Medical Journal* was the ideal that should be followed, but he felt that there was something about Washington that would do more for The Journal and the Association than seemed apparent. "If its great purpose can be accomplished in Chicago, let it remain; but, I repeat, the consciousness of Chicago is so immensely inferior to that of our political capital that I hope that all of us may see that the great destiny of the Association may more surely be accomplished at Washington."

Nicholas Seen, who was then in Milwaukee, asserted that a vote of the membership would show at least nine out of ten favorable to Chicago. Dr. T. D. Crothers of Hartford, Conn., warned that removal to Washington might destroy the publication and the Association. A few voices continued to echo the advantages of Washington, but by far the majority were now fully committed to remaining in Chicago. Dr. R. Harvey Reed took another hand in the battle in order to reply in extenso to Dr. Comegys; he continued to insist that there were hidden evil forces behind the movement to get The Journal to Washington. In fact he felt that there was a federal marasmus that is destructive of anything that gets into the nation's capital. He pointed out that the *Index Medicus* was published not in Washington but in Detroit and he announced that private business enterprises which were run on business principles stayed out of the national capital.

The editors of The Journal in the issue for April 4, 1891 began quoting editorial opinions from other medical periodicals; apparently the great majority of the leading medical publications of the country were convinced that Chicago was the desirable place for the publication.

The Board of Trustees met in the Arlington Hotel in Washington on Saturday, May 2, 1891. A questionnaire had been sent by Dr. R. H. Reed of Mansfield, Ohio, aided by T. D. Crothers, C. D. Beardsley and John F. Fulton of St. Paul. This questionnaire showed an overwhelming majority in favor of retaining the periodical in Chicago, actually a vote of 10 to 1, and E. D. Moffett of Indianapolis shouted in his letter "Remove The Journal to Washington—No. Remove Washington to The Journal."

The House of Delegates assembled in Washington, D. C., May 5. Immediately following the president's address the Board of Trustees made a preliminary report on the question of locating The Journal. They felt that there had been undue excitement, that sectional antagonisms had been engendered and that efforts had been made in stimulating the interest of lukewarm members.

The Board of Trustees on the second day of the session made an additional report. In this they pointed out that the editorial management of The Journal had continued as before, that the resident members of the Board had acted in the capacity of supervising editor, that they hoped to secure a building for the Association and that in view of increased funds they hoped to raise the professional and literary standards of its editorial department to the equal of any.

A special committee reported on the desirability of a cabinet appointment of a secretary of public health.

A resolution commended Dr. Hollister and the business manager, J. Harrison White, and recommended that they be employed for the ensuing year. It was considered, however, that this would not be mandatory on the Board of Trustees.

A committee was appointed to look into the question of incorporating the American Medical Association and to report in the following year.

Thus the furor over the transfer of The Journal from Chicago to Washington died without any battle in the House of Delegates. The ventilation of the subject in the columns of The Journal and the questionnaire to the membership by those opposed to the removal had been sufficient to settle the issue.

MEDICINE IN THE PRESS

Almost as if it might have been written yesterday are the following words from an editorial in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, July 4, 1891:

> It is apparent to even the careless reader of the daily papers that medical topics are receiving vastly more attention than ever before. It is even hinted that many large daily papers have a medical man on their regular staff; if such is the case they have generally succeeded in concealing the fact by displaying a phenomenal ignorance regarding medical subjects.

This was in connection with an article on the Keeley cure.

ELECTROCUTION

Early in July 1891 there occurred the first four executions by electricity in Sing Sing Prison. They were most satisfactory, at least to the observers, who said that death was instantaneous and painless in each instance. The doctors congratulated the warden and announced that this was unquestionably a method superior to any other yet devised for the purpose.

THE CORONER SYSTEM

In August 1891 appeared the first essay on the coroner system in the United States. Massachusetts was the first state to get rid of the coroner system and to introduce instead the system of medical examiners. The campaign to eliminate the coroner system is still waged in THE JOURNAL, but legislative bodies are loath to make this revolutionary change.

In his address to the Congress of American Physicians and Surgeons, Sept. 18, 1891, Dr. Claudius H. Mastin made it clear that there was no competition between that organization and the American Medical Association. He paid tribute to Samuel David Gross, who had participated greatly in the work of the American Medical Association and who was the founder of the Congress of American Physicians and Surgeons.

In the issue in which he published the proceedings of the American Congress, the editor of THE JOURNAL congratulated its readers on having such a good magazine.

ANDROLOGY BECOMES UROLOGY

About this time the urologists in the American Congress of Physicians and Surgeons constituted themselves into a section on andrology, which was to be contrasted with gynecology. The editor of THE JOURNAL felt that there was no future for this specialty as long as the general practitioners felt themselves competent to treat these cases.

1892

DETROIT

The periodicals provide the detail of thought and philosophy that prevail in any period. Thus an examination of the pages of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for the first half of the year 1892 indicates that the publication was being edited by J. C. Culbertson and that he was helped with editorials by Drs. W. S. Christopher, Chicago; T. D. Crothers, New Haven, Conn.; C. A. L. Reed, Cincinnati, and R. M. Wyckoff, Brooklyn.

THE BUSINESS COMMITTEE

Resolutions were proposed several months in advance of the session eliminating the committee on necrology and making the publication of obituary notices the duty of the editor of THE JOURNAL.

Dr. J. C. Culbertson proposed that all business matters of the Association be referred without discussion or comment to an executive committee composed of two members appointed by each state society in affiliation with the Association who should carefully consider and recommend such action as they might deem most advisable. This movement was to culminate in the system of reference committees which has been a feature of modern activities of the House of Delegates of the Association. Through the reference committees any member of the Association has opportunity to appear and express himself before final action is taken on any matter of significance.

POLIOMYELITIS

In 1891 Medin of Stockholm had reported an epidemic in which within five months 44 cases were observed in previously healthy children of a form of paralysis. This was one of the first great outbreaks of infantile paralysis definitely recognized as such; Dr. C. H. Hughes of St. Louis insisted in THE JOURNAL that it must be a form of grip.

THE DEPARTMENT OF HEALTH

Again and again during this year the medical profession was cheered with the belief that legislation would finally pass for the establishment of a department of public health in the cabinet. The measure had been introduced by Senator Sherman. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION had urged all medical societies, individual physicians and others to write to their senators and congressmen and to their special committees urging the passage of this legislation. It was felt that a strong response by the medical profession would ensure passage.

BEHAVIOR PROBLEMS IN THE HOUSE OF DELEGATES

In this period other problems of behavior had to be considered. Dr. Brodie of Detroit offered a resolution permitting the placing of books and other advertising sheets on the seats of members of the American Medical Association when they met in their annual session. This resolution was further amended by Dr. John H. Hollister, who requested that all material be protected by copyright in order to prevent pirating by other professions and other organizations. The first proposals for copyright had been made at the meeting in Nashville in 1890 and now came to fruition.

By this time also THE JOURNAL began urging doctors to bring their wives along to the annual session; the editor pointed out that if a member once did this he would never have another chance to go alone.

FOOD AND DRUG LEGISLATION

In this year also came the first proposals for suitable food and drug legislation to prevent adulteration. THE JOURNAL said that the establishment of a department of health should accompany such a food and drug administration, since under other circumstances it would have to go into the Department of the Treasury. Actually the evolution took just that form. Only in 1947 has a real department been proposed.

THE JOURNAL was having fun editorially with the Ohio legislature, which had rejected an appeal to regulate the practice of medicine in that state principally because it would interfere with itinerant doctors and diminish the advertising receipts of some newspapers.

The Ohio legislature, however, before adjournment did appropriate $5,000 to test the Keeley cure and made itself a sort of committee of the whole to investigate. Each member was to be privileged to send 1 patient to take the cure. Here and there the Keeley cure still raises its ugly head. But in 1947 "The Lost Weekend" and "Alcoholics Anonymous" mingled with psychoanalysis bring new aspects to alcoholism.

In May 1892 it was already recognized that registration of hundreds of doctors at the annual session was becoming a problem, and the proposal for registration by mail won great approval. This procedure was ultimately abandoned, only to be restored again in 1947 because so many thousands of physicians indicated they would attend the Centennial Session.

Toward the end of May the Philadelphia County Medical Society on the insistence of Dr. Solomon Solis-Cohen adopted resolutions urging THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and other leading medical publications to get rid of their proprietary medical advertising. The editor of THE JOURNAL defended the practice and hinted that THE JOURNAL might adopt the rule if the Philadelphia society would make good on the income which would be lost. However, he also defended the advertising of proprietary medicines on the ground that most physicians were prescribing great amounts of these preparations.

At this time American medicine was becoming subject to multiple organizations; the presence of these innumerable bodies was giving great concern to the leaders. In his presidential address Dr. H. O. Marcy of Boston urged that there was a place for all such bodies in American medicine. He emphasized particularly the need for two such groups as the American Congress of Physicians and Surgeons, consisting of organizations of specialists in many fields and of the American Medical Association to represent the great body politic.

THE JOURNAL had now reached a circulation of over 6,000 copies and was beginning to bring some income to the Association. Dr. Marcy traced in detail the development of the movement for a national department of health and expressed the hope that its ultimate establishment was not too far in the future.

At the 1892 session the movement to bring the New York state societies back into the fold culminated with the establishment of a committee for conference; at the same time a resolution was unanimously adopted directing the appointment of a committee to revise the Code of Ethics and the Constitution and By-Laws of the Association.

There was an extensive report by the committee that had been appointed to urge the establishment of a national department of health which ended with a recommendation that the committee be continued. Resolutions were adopted condemning the giving of testimonials for proprietary medical preparations. The committee on the Rush monument reported that the case was not entirely hopeless. It had received an encouraging donation of $300 from the exhibits at Nashville and the total contributions had now reached over $2,100, but it had only $646.81 left in the treasury. The minutes of the Board of Trustees indicate that Dr. Culbertson had been appointed editor on May 13, 1892. The Trustees had investigated the business of the Association and had made some radical changes. There was much correspondence submitted to the House of Delegates relative to incorporation of the Association, but the committee felt that the incorporation should be delayed until further evidence could be assembled.

It need not be thought that the path which the American Medical Association and THE JOURNAL was treading was entirely without obstructions or difficulties. The *New York Medical Journal,* through its editor, was waging a sort of guerrilla warfare. He ridiculed the quality of material brought before the American Medical Association and praised to the skies the societies of specialists. Nevertheless physicians throughout the country defended the American Medical Association on the ground that it was one organization primarily interested in the work of the general practitioner. The editor of the *New York Medical Journal,* although not a member of the American Medical Association, responded with a statement in which he pointed out that the leaders in American medicine did not attend the meetings of the American Medical Association; indeed, the editor of the *New York Medical Journal* felt that the one essential step toward advancement of the Association would be elimination of the entire Code of Ethics. Here came the old argument that a man would be a gentleman without any Principles of Ethics but forgetfulness of the fact that some men who are not quite gentlemen remain within the borders if they realize that there are no means for detection, trial and elimination.

THE JOURNAL was leaning in its content toward surgery; there were many discussions of proper preparation for specialization. While apparently the editors of THE JOURNAL had authority to omit papers without special interest for their readers, one finds innumerable manuscripts coming from the specialized sections so technical in character that they would be of immediate interest only to the advanced specialists in the fields concerned.

The eminent Dr. Keeley noted for his "cure for drunkenness" had arrived in London, and he was suing the *Lancet* and the *Press and Circular* for calling him a mischievous quack.

An unusual experiment was an attempt to transplant the skin of a black and tan dog to the head of a woman who had lost a major portion of the integument of her skull.

The desire to advance medical education was still having some troubles because the state board of health in Illinois was allowing a year of credit for study with a preceptor.

THE JOURNAL began to interest itself in the political aspects of the nation and to ask all doctors to find out where candidates stood on the national department of health issue before voting for them.

The committee on ethics submitted the entire code to the medical profession for criticism and with it the Constitution and By-Laws, asking advice as to how best to bring about the necessary revisions.

For the first time there appeared in THE JOURNAL the name of Victor C. Vaughan, the dean of the Medical Department of the University of Michigan, who wrote on "The Kind and Amount of Laboratory Work Which Should Be Required in Our Medical Schools." The discussion on his paper was extensive. But Bayard Holmes, who led the discussion, devoted his part of it mostly to drawings of histologic sections of the nervous system.

MEDICINE IN THE PRESS

Almost as if it might have been written yesterday are the following words from an editorial in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, July 4, 1891:

> It is apparent to even the careless reader of the daily papers that medical topics are receiving vastly more attention than ever before. It is even hinted that many large daily papers have a medical man on their regular staff; if such is the case they have generally succeeded in concealing the fact by displaying a phenomenal ignorance regarding medical subjects.

This was in connection with an article on the Keeley cure.

ELECTROCUTION

Early in July 1891 there occurred the first four executions by electricity in Sing Sing Prison. They were most satisfactory, at least to the observers, who said that death was instantaneous and painless in each instance. The doctors congratulated the warden and announced that this was unquestionably a method superior to any other yet devised for the purpose.

THE CORONER SYSTEM

In August 1891 appeared the first essay on the coroner system in the United States. Massachusetts was the first state to get rid of the coroner system and to introduce instead the system of medical examiners. The campaign to eliminate the coroner system is still waged in THE JOURNAL, but legislative bodies are loath to make this revolutionary change.

The eminent Dr. Keeley noted for his "cure for drunkenness" had arrived in London, and he was suing the *Lancet* and the *Press and Circular* for calling him a mischievous quack.

An unusual experiment was an attempt to transplant the skin of a black and tan dog to the head of a woman who had lost a major portion of the integument of her skull.

The desire to advance medical education was still having some troubles because the state board of health in Illinois was allowing a year of credit for study with a preceptor.

THE JOURNAL began to interest itself in the political aspects of the nation and to ask all doctors to find out where candidates stood on the national department of health issue before voting for them.

The committee on ethics submitted the entire code to the medical profession for criticism and with it the Constitution and By-Laws, asking advice as to how best to bring about the necessary revisions.

For the first time there appeared in THE JOURNAL the name of Victor C. Vaughan, the dean of the Medical Department of the University of Michigan, who wrote on "The Kind and Amount of Laboratory Work Which Should Be Required in Our Medical Schools." The discussion on his paper was extensive. But Bayard Holmes, who led the discussion, devoted his part of it mostly to drawings of histologic sections of the nervous system.

1893

MILWAUKEE

A reference to Garrison's "History of Medicine" indicates that the years between 1880 and 1900 were producing many important discoveries throughout the world; those fundamental discoveries are little reflected in the activities of the American Medical Association. True, there were discussions of treatment of diphtheria and of Koch's tuberculin. Lumbar puncture was introduced abroad in 1891, and several years later it had not yet been mentioned in The Journal of the American Medical Association. Particularly was The Journal lagging in its references to fundamental research in the laboratories of the basic sciences: the newer knowledge of bacteriology is little reflected in its pages. Leadership in medicine was still across the Atlantic.

By 1893 fifteen states in the United States had *established medical practice acts requiring examination* of all persons desiring to practice medicine. This movement had been received with favor; it was anticipated that soon all states would adopt such laws. An extraordinary editorial in January 1893 inclined to the view that Cohnheim was wrong in his theory of the cause of cancer and that it must be parasitic in origin.

An editorial early in 1893 indicates that the only way to improve the quality of The Journal is to make certain that members prepare and read better papers. Early in 1893 The Journal felt called on to condemn the House of Representatives for having removed the funds available for the publication of the Surgeon General's Catalogue from the Surgeon General's Library. Unfortunately succeeding congresses have been just as bad or worse. The Library was compelled year after year to move heaven and earth to obtain enough funds to operate the *Index Medicus* efficiently. Eventually the American Medical Association assumed the obligation and since that time has supported this necessary tool to medical research and advancement.

During the early months of 1893 correspondence waged back and forth on the Principles of Ethics. The discussions of the Principles of Ethics were rather one-sided with page after page occupied by some one who signed himself "A Conservative Member." It is difficult to determine with any certainty who this might be; the literary style resembles that of Nathan Smith Davis. The discussions were going on in New York pointing toward a meeting of minds on questions of dispute and it seemed likely that the vagrant members would soon be brought into the fold.

ANIMAL EXPERIMENTATION

About this time also The Journal began its editorials on animal experimentation, being particularly concerned because Lawson Tait in England had decided to side with the antivivisectionists; thus he did harm which many years would not be able to overcome.

As the year went on, The Journal published the new proposed Constitution and By-Laws and the new Principles of Ethics, which were to be the major subject of interest in the annual session in Milwaukee In presenting the revision of the Constitution and By-Laws The Journal urged acceptance of the concept that every member of a state society would be a member of the national organization and that the organization itself would be conducted by a delegate body. A feature of the Milwaukee session was the presence of Mr. Ernest Hart, editor of the *British Medical Journal.*

As correspondence on the Principles of Ethics continued, it became more and more apparent that there was no real reason to depart from Percival's code as it had been adopted by the Association in 1848 except for such minor modifications as needed to be made to meet some changing conditions. Yet some, including Edward Jackson of Philadelphia, felt that the Principles of Ethics were a bar to a real unity of the profession. The publication of the Principles of Ethics had resulted in only twenty letters, most of which dealt with such matters as the patenting of instruments and advertising by members of the profession. The Journal concluded, therefore, that "as the clamor for a change in the Code has not materialized in any widespread expression, and as the silence of 99 per cent of the 7,000 members of the Association ought to be counted in favor of satisfaction with the present status, further and detailed consideration of the proposed amendments might be omitted."

Dr. Hunter McGuire, President of the Association, in his address in Milwaukee, June 6, 1893, felt it desirable that both the Constitution and By-Laws and the Principles of Ethics lie over for a year so that the views of the individual states might be ascertained. He concluded his address by urging again the establishment of a national department of health.

The committee on creating a department of health in the government reported progress, particularly because Grover Cleveland in dedicating the building of the New York Academy of Medicine had made most complimentary remarks about the medical profession.

The Trustees were having a little trouble about publishing The Journal because the Association had adopted a resolution calling attention to the fact that the Code of Ethics prohibits all commendatory mention or reference to secret preparations. The Trustees neatly passed the buck by instructing the editor that "when the editor is in doubt of the character of an advertisement, he shall refer the same to the committee on advertising, and that an advertisement of a proprietary medicine shall be accepted in the discretion of the committee when the proprietors thereof shall furnish the complete formula."

The main business of the session was the consideration of the Constitution and By-Laws, on which there were majority and minority reports. However, the whole procedure had, in any event, to lie over for a full year. The same man who presented a minority report on the Constitution and By-Laws, Dr. Henry D. Didama of New York City, presented a minority report on the Principles of Ethics. The situation was, however, well under control. Debate was stopped by the presentation of a report by N. S. Davis of the committee to confer with committees of the Medical Society of the State of New York and the Medical Association of the State of New York. This indicated that there had been no conferences because it seemed likely the situation was well in hand in New York State.

Eight hundred and sixty-seven physicians had registered at the meeting in Milwaukee. The Journal pointed out that the entertainment had been superb and that the new Pfister Hotel was not surpassed for elegance by any hostelry in any city, being only favorably compared with the princely Waldorf in New York City.

Four new Trustees had been elected, and the editor was not a candidate for reelection, so that his official relation with The Journal ceased with the last issue of June 1893. The editor called attention to the difficulties in maintaining membership in relationship to subscription to THE JOURNAL and also to the need for a new legislative body which would be truly representative. THE JOURNAL was confronted with an enormous list of delinquents. Apparently one member, Dr. R. Harvey Reed, had circulated a letter to all the Trustees and officers in Milwaukee calling attention to the fact that THE JOURNAL was in debt $10,000. This the editor classifies as a "dastardly falsehood," since THE JOURNAL had never been in debt $1 beyond the cash funds in the hands of the treasurer. In leaving, Dr. Culbertson announced that he planned to resume his connection with the *Cincinnati Lancet Clinic* and that his latch string would be out in Cincinnati for all the members of the American Medical Association. Dr. John B. Hamilton, who resigned immediately as Trustee, succeeded to the editorship of THE JOURNAL following the retirement of Dr. Culbertson, who had a long list of editorial contributors, including such distinguished names in the Chicago area as those of Harry Gradle, Bayard Holmes, G. Frank Lydston, Harold N. Moyer and George W. Webster and from outside the Chicago area such men as Hobart A. Hare, G. Betton Massey and Frank Woodbury.

One finds for the first time the name of J. L. Rosenberger Esq. He was for many years responsible for the abstracts of medicolegal decisions, which has come to be one of the most important features in the makeup of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Dr. Hamilton had previously been editor of THE JOURNAL for a brief period; it is not surprising to see that the change in editorship did little toward improving the makeup or quality of the material in the publication.

The preparation of students for entrance into medical schools was still far below the quality needed to ensure culture. Here are a few examples quoted in THE JOURNAL of essays contributed by students immediately following their graduation:

> Treatment of eclampsia: "To keep the patiant from stricking his head or limbs against and place the patiant in a horzontal position to favor respration circulation. Give bromide of potass. to act as a direct sedative or to excite motor susceptibility of the medula oblongata of the nerve centeres and keep perfect qeuiet."
>
> "Cholor infantum is due to a tomen symtom comences with Diarrhea first stools partly soft yet Liquid and stains the clothing a green color with a musty Odor vomiting pain and Rise of temperature and rapid prostration. May efect the brain when the patiant Roles heat and sleep with eyes open give Bromide potass for this first give Hyd chlor mit in small doses every hour and epecac at first and then Bismuth and Shlicylyc acid give stimulent to keep up the strenth."
>
> "In false croup the farinx is not involved there is false membrane we dont get the spasms."
>
> "There are 3 Verietys of pnemonia lobor Lobular interstiscial lobor is where we have all the lobes of the lung involved we have 3 stages. The inflamation extends from below upwards the seat of inflamation is in the alveoli or air vescle. Stage of ingorgement last 24 to 70 days red hepatization 5 days."
>
> "The Teory of diebetis is an cretation upon the floor of the 4th ventrecle, may be do to Violence or High liveing."

Significantly Mr. Ernest Hart before departing for Great Britain gave an interview to the editors of THE JOURNAL in which he pointed out that an increase in the membership of the American Medical Association would automatically result in an improvement in THE JOURNAL. He said "Better papers, more condensation and a larger wastebasket would naturally follow an extended membership." Mr. Hart was convinced that the American Medical Association should have the strongest association and the best journal.

Within a few months THE JOURNAL began to make improvements, adopting some black letter side headings which gave it a much more lively appearance. An interesting essay is contributed by Dr. James B. Herrick, published July 22, 1893, with his observations on an experience with nearly 1,000 cases of typhoid. These were all seen in the Chicago area. In 1945 there were only 13 cases of typhoid in the entire area (now with a population of 3,500,000) and there were only two deaths.

In 1893 Grover Cleveland became ill. He was attended by Dr. Joseph P. Bryant, who refused to give a detailed statement of the President's illness to the reporters. At once the press set up a terrific howl against the Principles of Ethics, which, incidentally, had nothing whatever to do with the case. The editor of THE JOURNAL felt that the responsibility was not at all that of Dr. Bryant but of the family to give to the press such information as it cared to give.

About this time THE JOURNAL apologized to Dr. R. Harvey Reed of Mansfield, Ohio, for the editorial that had been published by Culbertson. It turned out that Dr. Reed had limited the circularization of his letter and had sent it only to the business committee.

Interesting in this period was the announcement by Dr. John B. Murphy of his button for anastomosing the intestine. The button was at that time a medical sensation.

In New York there was a physician named Robert Lincoln Watkins who was convinced that the germ of tuberculosis was not the cause of the disease. He inoculated himself with a pure culture of the organisms, and THE JOURNAL editorial described him as a "crazy physician."

In the meantime Dr. John C. Culbertson and some of his friends were circulating editorials attacking the American Medical Association, and THE JOURNAL was endeavoring to build up the membership by calling attention to the improved quality of the scientific work and of the publication itself. THE JOURNAL did much to promote the great Pan American Medical Congress that was held in that year in Washington. Incidentally it is amazing that more people did not go because the hotels were charging from $4 to $4.50 a day American plan. The addresses given at the Pan American Medical Congress appeared for the most part in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and they represented about the best that American medicine could develop. They were of great aid to the quality of THE JOURNAL.

An amusing item describes the excursion train that left Chicago for Washington, which was wrecked near Indianapolis. Dr. G. Frank Lydston devoted several pages to "Muscle Building as Illustrated by the Modern Samson, Sandow" in which he concluded that "Sandow is a wonderful man, but his example is pernicious." Lydston was well in advance of his time in recommending play for exercise rather than muscle culture.

In its coverage of the Pan American Medical Congress, THE JOURNAL printed letters describing the trips and the guests on every one of the special trains that went from Boston, Detroit, Cincinnati and Chicago. The people on the special trains were entertained en route. In Chicago they had a breakfast at the Palmer House which was mixed up with a breakfast at the Auditorium. Dr. Fernando Henrotin welcomed the visitors in French, Dr. E. J. Gardner in Spanish and Dr. John B. Hamilton in English. At 8:30 in the evening they had a party at Kinsley's, where a male quartet sang funny songs and a mandolin orchestra furnished instrumental music. Then they visited the Chicago Medical College and the Cook County Hospital and all of the other medical schools.

In November 1893 the state of New York began to get rid of its coroner system and to follow the examiner system of Massachusetts.

In its last issue for the year, the editor of The Journal has one of the most amusing editorials published in the entire history of the organization. A special correspondent of the *British Medical Journal* had called the attention of that publication to the fact that America lacked independent medical journals controlled by medical men and that it lacked also a national or unitary organization. The *British Medical Journal* therefore addressed a communication to the prominent members of the United States offering them the *British Medical Journal* for $8 a year. This annoyed the editor of The Journal, who replied by pointing out that The Journal of the American Medical Association, while it took legitimate advertisements, kept them in the columns devoted to that purpose and did not supply reading notices as was customary in the British publication.

1894

SAN FRANCISCO

With the beginning of 1894 the editor of The Journal began circulating sample copies to men who were not subscribers with a view to increasing the circulation. In the same issue Dr. N. S. Davis remarked bitterly about the manufacturers of Maltine, who used his picture on a calendar which they circulated to the medical profession. He said "As I have never prescribed an ounce of Maltine nor written a line concerning it in my life, I assume the manufacturers have taken this method to inflict punishment. And certainly they could not have devised a more contemptible or meaner method if they had searched the records of meanness for half a century." The old gentleman must certainly have been angry on this occasion.

The editor of the *New York Medical Record* challenged some of the statements that were used by The Journal in giving an impression as to the amount of reading material that it gave to the readers. By actually counting the words on the pages, the editor of The Journal proved that The Journal of the American Medical Association was the largest medical journal in America. He challenged the *Record* by telling it that The Journal had only just started; the editorial ended with the words "Just wait."

In a long letter to The Journal Dr. N. S. Davis supported the changes that were being proposed for the Constitution and By-Laws; he thought that the time had just about come to stop tinkering with the Constitution and By-Laws.

The editor of The Journal was alert to protect the interests of the publication. In a brief note he told the editors of the *Philadelphia Medical News* and the *Pittsburgh Medical Review* to mind their own business because they ran an editorial objecting to publication in The Journal of an article in two parts. Those were the days of competitive journalism in American medicine, and the battle raged continuously. A week later the editor told the editor of the *Pittsburgh Medical Review* that his ill natured commentary on a note published in The Journal was unwarranted.

A notable feature of The Journal of the American Medical Association for March 24, 1894 was the clinical history of the case of President James A. Garfield by his physician, Dr. Robert Reyburn, who gave a complete description of his case—one of the most important historical documents in its field and yet one hardly mentioned in historical or biographic writings in this country.

In The Journal for March 31, 1894 an article on the psychophysical relations of man considered from the standpoint of a professor of medicine is just about as modern a review of psychosomatic medicine as can be found in periodicals current in 1947.

FRAUDULENT MEDICAL COLLEGES

On March 31, 1894 the Illinois State Board of Health compiled for The Journal of the American Medical Association a list of fraudulent medical institutions. This was the first of the important articles which were to do more to raise the standard of medical education and eliminate low grade medicine in the United States than any other factor.

PROPRIETARY MEDICINES

The medical profession was beginning to be increasingly aware of its responsibility in the promotion of proprietary medicines. Dr. Solomon Solis-Cohen of Philadelphia initiated this fight and constituted himself the leader of the crusade. He was attacked in a vicious letter published in The Journal of the American Medical Association for March 24, 1894, which indulged in personalities as to his race and religion. The writer, whose communication was anonymous, said that he would just as leave use Listerine and Phenacetin until the Pharmacopeia gave him something to take their place. By March 31 half a dozen writers alined themselves with Dr. Solomon Solis-Cohen in this crusade. The majority of physicians already favored the elimination of "patent" medicines and low grade proprietaries from the advertising columns of The Journal. Apparently, "Medicus," who wrote the anonymous letter, overplayed his hand. Issue after issue of The Journal condemned him for conduct that was unethical in his attack on Dr. Solis-Cohen and for being anything but a gentleman. By the virulence of his attack he rallied to the support of Dr. Solis-Cohen many who might otherwise have paid little attention to the controversy.

PIRATING JOURNAL ARTICLES

The editor of The Journal called the attention of his competitors to the fact that the papers read in the annual session were the property of The Journal. Already competitors were asking authors for their papers, offering to publish their articles, to put them in type and to give them free reprints if they would only pull their articles out of The Journal of the American Medical Association.

Early in May 1894 the Washington correspondent of The Journal telegraphed that "Coxey's army," 437 men and 30 horses, fatigued and improperly and scantily fed, without shelter, was camping in an enclosure of 60,000 square feet, recently drained, containing five decomposing manure dumps and abutting on James Creek. There were foul smelling, open sewers and many filthy gutters; there was no shade, and the temperature was about 90 at 10 p. m. The health of the "army" and city was threatened. The editor of The Journal pointed out that some better place should have been found for General Coxey's army and that the animals at Rock Creek Zoo were better cared for.

ATTACKS ON THE PRINCIPLES OF ETHICS

The discussions on the revision of the Principles of Ethics were growing sharp; many of the older leaders of the American Medical Association began to express themselves with such pseudonyms as "Conservative Member" and "Harmony," while Dr. N. S. Davis kept pointing out that the Principles of Ethics were a part of the fundamental law of the Association and that they could be amended only with the same seriousness as the Constitution and By-Laws.

The address of the President, Dr. James F. Hibberd of Richmond, Ind., was concerned wholly with associational affairs and particularly with the desirability of membership in county and state societies as the basis for representation in the American Medical Association. He was glad to report that the Congress had been made to see the importance of the *Index Catalogue* and to continue the appropriation for its publication. Again he urged the establishment of a department of health in the cabinet. It seemed to him that the future of medicine would be along biologic lines and that biology must be more and more the basis for training in medicine.

The San Francisco session had taken many significant actions. The business of the Association had increased to include a budget of more than $35,000, a figure which was to grow with the years, so that the next fifty years saw this $35,000 grow into millions.

The state medical societies had been asked to consider the Principles of Ethics. Twenty-one had reported opposition to any change; two reported in favor of a change, and two recommended that the subject be laid on the table.

THE TREASURER

Dr. R. J. Dunglison had been for seventeen years the faithful and energetic treasurer of the Association without compensation. A resolution was offered by E. E. Montgomery of Philadelphia that he be given an honorarium of $300 and this was referred to the Board of Trustees.

THE LIBRARY

At this meeting the librarian suggested that the library of the American Medical Association be turned over to the Newberry Library in Chicago, to which Nicholas Senn had previously given his complete library.

ADVERTISING IN THE JOURNAL

The Board of Trustees reported that they were receiving cancellations of five subscriptions daily at the time when Dr. John B. Hamilton became editor but that following his assumption of the editorship The Journal began to increase in size and was thereafter more successful as an advertising medium. The Board of Trustees felt that it was necessary for them to take some action on the quality of advertisements. The Board found itself in a difficult position. It needed the advertising to pay for The Journal but it had a resolution from the membership that advertisements should not be accepted for any secret proprietary remedies. They therefore took as their standard what other journals were doing.

The new Constitution and By-Laws came up for consideration. Again Dr. H. D. Didama presented a minority report and his minority report, by vote, became the report of the committee. This threw the entire organization into an uproar. Speeches were made by many of the leaders. Apparently no one was quite certain as to just what had happened, because it ended with the By-Laws being allowed to remain over until the following year. When the consideration of the Principles of Ethics was called up, Dr. Didama again presented a minority report and his minority report was adopted. A motion was then made to lay the whole question on the table, and this motion passed.

The committee that was trying to get a secretary of health for the cabinet was given $400 to go down to Washington and urge its cause.

Then came a battle resulting from a resolution introduced by Edward Jackson of Pennsylvania over the admission of advertisements of proprietary remedies to The Journal.

In the same issue as appear the minutes of the San Francisco session of 1894 is a report on the question of advertising. This report points out that most of the criticism had come from the *Medical News* of Philadelphia, which was printed by a Philadelphia publisher. This Philadelphia publisher had wanted to get The Journal under his control. The *American Lancet* defended the Trustees in their policy to keep on publishing somewhat doubtful advertisements, but it felt that this would cost The Journal $8,000 a year and that the sacrifice was hardly warranted.

The Medical College Association at this time expelled two of its constituent colleges for failing to comply with rules governing the graduation of medical students.

SIGNED REVIEWS AND EDITORIALS

Among the editorial contributors added to the staff in 1894 one finds the significant names of W. A. Pusey and John A. Wyeth. At no time in its history has The Journal published signed editorials or book reviews. The question has been repeatedly agitated in the columns of The Journal and before meetings of the Board of Trustees. Without doubt the adoption of this policy has resulted in a freedom of expression in editorials and book reviews which has been for the advantage of American medicine.

RAILROAD TROUBLES

The record of the return home of former President Hibbert from San Francisco to Indiana indicates that travel in that day of the great railroad strike partook of the hazards of pioneer overland trails. The trains and their arrivals and departures resembled a great deal the kind of delays that accompany long airplane trips in these times. Dr. Hibberd's travel was complicated; the train moved along in jumps of 25 to 50 miles. Chicago was cut off entirely from railroad travel. Stages carried the party over the crest of the Rockies; it took from five to seven days to go from Helena, Mont., to St. Paul. One hundred and seventy physicians found themselves unable to leave Yellowstone National Park and failed to receive any mail for ten to fifteen days.

Now began an agitation which was to make obstetrics and gynecology specialties in medicine. The general surgeons revolted and argued that a woman's liver and intestines and stomach were just the same as those of a man and that the general surgeon could do everything necessary surgically in the abdomen, male or female.

Dr. Hamilton devoted himself strongly during the latter half of 1894 to building subscriptions to The Journal. Every issue urged doctors to subscribe. Premiums were offered to medical students who could secure subscriptions.

THE JOURNAL FINDS A NEW PLANT

In September 1894 The Journal moved from its quarters on Wabash Avenue in Chicago because the new library building cut off the light and air, making it necessary to burn the gas continuously for the last six months. Because of the cramped quarters it had been necessary to have the editorial work done elsewhere. The editor had been authorized by the trustees to secure better accommodations; the new offices were in the *Times* Building at 84-86 Fifth Avenue (now known as Wells Street). The Journal purchased its own presses (the best and fastest that could be purchased at the time) and the remainder of the machinery was of the latest and best pattern.

Dr. Hamilton was still combative; he ended his editorial with the statement:

> Carping critics have not infrequently amused themselves by predicting the downfall of The Journal, but, supported by the Association, it has continued to prosper beyond the most sanguine hopes of its best friends.

In another editorial Dr. Hamilton wrote:

> A medical gentleman on whom a Journal representative called said that he did not care to belong to the Association "because," said he, "the organization is simply a mutual admiration society." Exactly so, and if our fugacious friend wishes to be thoroughly admired, he too should join the Association and assist in the noble work of making it the greatest medical organization the world has yet known.

The editor pointed out that the new press would print 2,300 impressions an hour and that another press would print 2,000 an hour. The Board of Trustees of the Association has more recently authorized the expenditure of some $250,000 to purchase one new rotary press capable of printing ninety-six pages at one time and of turning out 6,000 two-color impressions an hour.

On October 7, 1894 Dr. Oliver Wendell Holmes, the genial autocrat of the breakfast table, died at the age of 85. His passing received editorial comment in every medical journal of the nation. The editor of The Journal called attention to his "famous report of the committee on medical literature." He had participated in the work of the founding and development of the American Medical Association, and his contributions to medical advancement insured him a prominent place in medicine's hall of fame.

In his message to the Congress in December 1894 President Grover Cleveland recommended the establishment of a national board of health and a national health officer. Alas, the years have passed and this vain hope is not yet realized. It continues to be one of the leading planks in the platform of the American Medical Association.

(To be continued)

Clinical Notes, Suggestions and New Instruments

UNUSUAL REACTION FOLLOWING BENADRYL ADMINISTRATION

JACOB GEIGER, M.D.
S. ZELMAN ROSENFIELD, M.D.
and
DANIEL L. HARTMAN, M.D.
New York

Numerous toxic reactions, of a relatively mild nature, have been reported following the administration of Benadryl.[1]

Drowsiness, dizziness, weakness and nausea are those most frequently encountered. Sixty-three per cent of the patients in one series[2] experienced side reactions, the chief one being drowsiness of varying degree up to narcolepsy. In view of the extensive and almost indiscriminate use of Benadryl at the present time, the following case history should be of general interest.

REPORT OF CASE

R. S., a white woman aged 26, was admitted to the First Medical Service because of a generalized seborrheic dermatitis of unknown origin. The lesions involved almost the entire body, including the face. On admission the temperature was 103.2 F. (rectal), the blood pressure was 90 systolic and 60 diastolic, and the pulse rate was 90. The blood count was normal. The lesions of both feet and both legs were secondarily infected. The patient was given penicillin intramuscularly (25,000 units every three hours), ephedrine orally ⅜ grain (0.243 Gm.), three times a day, and supportive vitamins orally; both legs were elevated and warm magnesium soaks were used. The temperature fell to normal levels on the third hospital day, and the administration of penicillin was discontinued on the fifth hospital day. On the fourth hospital day, the administration of Benadryl (50 mg. three times a day) was begun to combat the decided pruritus. After receiving a total of 300 mg. of the drug over the course of three days, the patient complained of palpitation, dimmed vision, malaise without drowsiness and heartburn with nausea. Following the next regularly scheduled dose of Benadryl (making a total of 350 mg.), the patient was found unconscious in bed, cold, pale and pulseless. The blood pressure could not be obtained. The eyes were staring, but the pupils were equal and reacted to light. A solution of epinephrine (7½ minims [0.46 cc.] in a 1 : 1,000 dilution) was given subcutaneously, and all medicaments were stopped. Within thirty minutes the pulse was palpable, though weak, and the patient responded to painful stimuli. In three hours the patient was completely normal, with no recollection of what had happened. The following day the magnesium soaks, the supportive vitamins and the oral dosage of ephedrine were reinstituted and the patient continued to improve. On the eleventh hospital day, the administration of Benadryl was again started under careful observation. Again, after 300 mg. of benadryl were taken over a period of three days, the patient began to complain of palpitation, severe malaise, dimmed vision and nausea. On examination she was observed to be somewhat disoriented and excited. The pulse was weak, the skin was pale and the blood pressure was normal. Benadryl was immediately discontinued, and within two hours the patient felt entirely normal. The skin had returned to its normal color, and the pulse was full and regular.

This appears to be a shocklike reaction to Benadryl not previously reported.

1070 Park Avenue, New York 28—114 East Thirty-Seventh Street, New York 16—320 Concord Avenue, New York 54.

From the Medical Service, Lincoln Hospital, Leander H. Shearer, M.D., Director.

UNUSUAL SIDE EFFECT FROM BENADRYL

HARRY R. WEIL, M.D.
Milwaukee

There have been various reports of side effects of beta-dimethylaminoethyl benzhydryl ether hydrochloride (Benadryl).[1] These reports describe, among others, symptoms of nervousness and/or of hyperirritability. McElin and Horton[1a] reported several cases of difficulty in coordination; Waldbott,[1b] muscular twitchings, and Levin,[1c] narcolepsy, confusion, jitters and irritability. This is the report of a case in which the symptoms of nervousness, difficulty in coordination and muscular twitchings were present to the extent of epileptiform movements.

REPORT OF A CASE

J. H. W., a white boy aged 3½, weight 33 pounds (15 Kg.), had symptoms of hay fever for the first time in August and September 1945. Scratch tests confirmed sensitivity to ragweed (giant and short varieties) only, and in December 1945 treatment was instituted for hyposensitization. Treatment was given until June 9, 1946, and then the child left town. At that time he was receiving 6,000 pollen units of mixed giant and short ragweed. Aside from hay fever, the history was noncontributory and physical examination was negative. On Aug. 30, 1946, several weeks after the child had returned to town, he began to manifest mild signs of hay fever, with rhinorrhea, conjunctivitis and sneezing. By Sept. 3, 1946 the symptoms were severe enough to warrant the parents in bringing him to my attention. Benadryl, 50 mg. every morning and at bedtime, was prescribed and gave good, though not complete, relief. At 6 p. m. on September 6 the patient was given a 50 mg. capsule of the drug, and shortly thereafter he went to bed and to sleep. His attitude at this time was considered normal by the parents. At midnight the child awakened with a severe sneezing attack. To alleviate this, he was given 2 capsules of Benadryl (100 mg.) and returned to bed. At 12:20 a. m. the child was found sitting up in bed, singing, laughing and starry-eyed. He did not obey requests to lie down and to be quiet but, instead, laughed and "acted as though he were drunk." At this time muscular twitchings of the face and involuntary spastic movements of the extremities were first observed. Shortly thereafter there was urinary incontinence. In about ten minutes (by which time I was in attendance) the involuntary muscular movements of the face and extremities were more pronounced and the child was irrational—not knowing where he was and not recognizing his parents. At this time he "dove" from his bed to the floor. Although he landed on his head, he laughed as he was picked up and put back to bed. Physical examination at this time was negative except for (1) muscular twitchings and purposeless movements of the extremities; (2) hypertonic patellar and triceps reflexes (corneal, cremasteric and abdominal reflexes were considered normal), and (3) irrational speech gradually becoming slurred.

One and one-half grains (0.09 Gm.) seconal was administered by mouth, and within fifteen minutes the child was sleeping fitfully. Muscular twitchings and athetoid movements continued, and on moments of awakening the speech was slurred past the point of understandability. On several occasions in the next three hours the child attempted to "dive" out of bed and was restrained. About 4 a. m. the child sat up and spoke clearly but still showed evidence of muscular spasm and hypertonic reflexes. In about fifteen minutes he fell asleep and slept fitfully until 9 a. m. The effects of seconal (?) (sleepiness, unsteadiness and anorexia) were evident until after the 2 to 4 p. m. nap. At this time (4 p. m.) the child was further examined and considered normal. The reflexes were normal, the gait was normal and conversation was rational. There was no memory of the activity of the evening and early morning.

COMMENT

Some of the activity which came on after the administration of seconal may be attributed to that drug. There was no history of any equivalent episode prior to the administration of 100 mg. of Benadryl; and since then, as before, the child has taken 50 mg. of Benadryl up to four doses a day without any side effects. There has not been any effort to date to repeat the 100 mg. dose of the drug. The practitioner should adhere to the accepted dose of Benadryl for children, i. e., 2 mg. per pound of body weight.

PROLONGED REACTION TO BENADRYL

SAMUEL SCHWARTZBERG, M.D.
and
DARRELL WILLERSON, M.D.
San Antonio, Texas

Benadryl, beta-dimethylaminoethyl benzhydryl ether hydrochloride, became available to the public in March 1946. Since that time it has become widely used for various types of allergy, the demand not infrequently exceeding the supply. While side reactions to the drug are common, definite toxic or allergic reaction has not previously been reported, although 3 possible cases of spontaneous asthma resulting from its use were reported by Waldbott,[1] and a vasospastic condition involving the fingers of one hand was reported by Friedlander and Feinberg,[2] but the condition was thought to be coincidental. Side reactions are normally expected, despite the fact that they are sometimes severe enough to necessitate discontinuance of further treatment. Side reactions previously reported are: drowsiness, sleepiness, nervousness, dryness of the upper respiratory passages, weakness, fatigue, ataxia, facial edema, urinary frequency, nausea, epigastric distress, bad taste, a tendency to bleed, a sense of relaxation, tingling of the extremities or body, tinnitus, chilliness, pruritus, a taste like chloroform, faintness, acute hysterical reaction, dilated pupil,[3] stupor, narcolepsy, confusion, blurred vision, sore tongue, pallor, hot flushes, aggravation of allergic state, irritability, palpitation, exhaustion, collapse, somnambulism, dizziness, numbness, cold extremities[4] and muscular aching.[5] To these may be added headache and acute melancholia (2 cases, 1 with uncontrollable crying in the fourth month of pregnancy). Side reactions promptly disappear with discontinuance of the drug.

An unusual and prolonged reaction to Benadryl was encountered April 19, 1946.

REPORT OF CASE

History.—J. E. H., a white man aged 38, had a chief complaint of swelling of the eyelids, lethargy, numbness, tingling and a feeling of swelling in the hands, deep soreness of the center of the forearms and a feeling of swelling and tightness of the upper arms. On March 23, 1946 he procured one hundred 50 mg. capsules of Benadryl on the advice of a physician friend for the relief of hayfever. He was told by a drug salesman that he could take one whenever the effect of the previous capsule had worn off. The first capsule was taken March 24, while he was traveling. Moderate drowsiness ensued while he was driving, and he did not take any more that day. During the next three weeks he sometimes took from one to three capsules a day; some days he did not take any, but he usually took one or two, and never more than three. The last capsule was taken April 13, which made a total of twenty-three capsules in twenty days. About one week after starting the Benadryl, the patient noticed puffiness of the eyes, and the occurrence of three stools a day, together with considerable amounts of flatus. He had previously been mildly constipated. The stools were lighter in color than normal but well formed. Toward the end of the second week a feeling of tightness was noticed in the arms from the shoulders downward, hands and, to a slight extent, behind the knees. On gripping the fist or shaking hands, discomfort was noticed along the center of the forearm to the elbow and was most pronounced at the center of the flexor surface of the wrist and just beneath the antecubital fossa. The hands felt numb, with prickly sensations present, and the patient had difficulty in working with small tools because he dropped them so frequently. Thought processes had slowed considerably: The patient didn't feel alert and didn't like to talk to people because of difficulty in coordinating thoughts and speech. He told his customers that he was not well and to disregard anything silly that he might say. He felt weak, groggy and sick.

[5] Curtis, A. C., and Owens, B. B.: Beta-Dimethylaminoethyl Benzhydryl Ether Hydrochloride (Benadryl) in Treatment of Acute and Chronic Urticaria, Univ. Hosp. Bull., Ann Arbor **11**: 25, 1945.

The patient continued at his work of installation of x-ray machines, except for two or three days when he felt utterly incapable of working, because these machines were urgently needed at the military hospitals and there was no one to help or replace him. He finally came to the conclusion that the Benadryl might be causing his trouble, and it was discontinued. He consulted his physician on April 19, six days after the last capsule was taken. The only other drug used during this period was privine hydrochloride nose drops. These were discontinued by the physician, but were prescribed at a later period without ill effects.

Physical Examination.—The sallow pallid skin, the puffy eyes and the sick look of the patient were striking. The first thought of the physician was of nephritis. The patient was above the average in intelligence and gave an unusually good history, although speech was slow and slightly slurred. The only objective observations were a blood pressure of 100 systolic and 64 diastolic, edema of the eyelids, tenderness over the median nerve in both forearms and questionable edema of the forearms and hands. Examination of the fundus of the eye by an ophthalmologist [6] was negative. Evidence of papilledema or increased intracranial pressure was absent. Tests of epicritic sensation, pain on heat and cold, muscle tendon and joint sense, light touch and astereognosis revealed normal responses. Gait and reflexes were normal. Muscular wasting was not observed, but some muscular weakness of the forearms and hands was evident. Urinalysis and a blood count were within normal limits. No eosinophils were present. A scratch test with Benadryl powder gave a weak positive reaction, as did an intradermal test with a 1:100 solution of the drug. The same reactions were obtained on a normal control who had never taken Benadryl and are without significance. Treatment was not given, but intravenous histamine was elected as the treatment of choice if the condition failed to improve.

Progress Notes.—The patient began to notice slight improvement on April 21. The tendency to constipation had returned. He did not feel quite as groggy. On April 29 he felt much better and stayed up until 11 o'clock at night, instead of going to bed at 8 o'clock, as he had been doing since the onset of his illness. Mentally he was more alert. The tightness seemed to be localized about the junction of the middle and upper third of his arm. Puffiness of the eyes was less pronounced and the color of the skin was closer to normal. The hands still felt somewhat numb and he could not grip things well. The blood pressure was 124 systolic and 90 diastolic. By May 31 the condition had greatly improved. Weakness and discomfort of the wrists and elbows when carrying objects were present, but the prickling sensations in the hands were present only occasionally. His mental alertness was nearly normal. On July 15, the patient stated that within the preceding one or two weeks he had felt absolutely normal from a standpoint of mental alertness. There is still slight discomfort beneath the right antecubital fossa on carrying heavy objects or on great pronation of the forearm.

COMMENT

It may be noted that most of the symptoms appear to be an intensification of the normally expected action or side reaction of Benadryl. The lowered blood pressure is a normal action of this drug.[2] The gastrointestinal symptoms may be readily explained on the basis of decreased histamine and decreased secretion of the stomach as a result of Benadryl.[3a] Edema has been observed among the side reactions [3c] of the drug. The mental lethargy, drowsiness and weakness appear to be intensifications of side reactions. Numbness and tingling of the extremities are normal side reactions. Pallor has been observed among the side reactions.[4] The neuritic symptoms alone have not been previously reported in human beings. However, Parke Davis and Company [7] has reported polyneuritis in dogs following 5 mg. of the drug per kilogram of body weight given intravenously, when the dose is repeated daily. Neuritic symptoms and signs subsequent to the use of drugs are not unusual. Over 100 cases of various types of neuritis have been reported following the use of the sulfonamides.[8] Other cases of neuritis have been reported following the use of Hapamine [9] (a chemical combination of histamine and depreciated horse serum globulin) and various serums and extracts, especially tetanus antitoxin.[10] Opinion is divided as to whether the neuritic symptoms are on the basis of toxic effect or allergic edema. Whatever the mechanisms in this case, the manifestations are toxic and appear to be closely linked to the normal cellular action of the drug. The present trend is to view the action of Benadryl as displacing histamine in the tissues.[11] Pyribenzamine (N'pyridil-N'benzyl-N-dimethylethylenediamine), the sulfonamides and histamine derivatives are now thought to act similarly by displacement.[12] Whether a cumulative effect of the drug was present is unknown. It would seem likely.

DANGER WITH BENADRYL OF SELF MEDICATION AND LARGE DOSAGE

MILTON C. BORMAN, M.D.
Milwaukee

Slater and Francis recently reported the use of Benadryl (beta-dimethylaminoethyl benzohydryl ether hydrochloride) as a contributing cause of an accident.[1] They called attention to the frequency of drowsiness as a side action of the drug. The following report of a case illustrates the danger of self medication and large dosage.

REPORT OF CASE

A convent nun, aged 18, had been under my care for a year because of obesity and menstrual difficulties. She had had attacks of asthma since childhood, which were worse in ragweed season and early winter than during the rest of the year. She was given a prescription for forty-eight 50 mg. capsules of Benadryl. At the convent she was allowed to keep the medicament in her own room. She took two of the capsules, as prescribed, the first day, with decided relief. She felt so much improved that the next day she decided to take the capsules oftener. During the following three days a total of forty capsules disappeared. She stated later that she had taken all of them. None were recovered in her room or in other parts of the convent where she had been. She became drowsy and began to act queerly. She dropped clean clothes in the laundry, left her tasks partially completed, wandered off into other parts of the convent and did not remain in her bed at night. During "instruction period" she asked another Sister to pass the salt. Her temperature, pulse and respiratory rate were normal. She was lethargic, confused and disoriented. The heart sounds were normal. The blood pressure was 120 systolic and 80 diastolic. Fluids were given freely, including several cups of strong coffee during the day. For two nights she had "suffocating spells" but had no other complaints. Within forty-eight hours she had made an apparently complete recovery.

SUMMARY

Although there is no absolute evidence that the patient whose case is herein reported took 2,000 mg. of Benadryl in forty-eight hours, her general condition indicated overdosage and illustrates the danger of self medication with this drug. It is of further interest that two 50 mg. tablets taken in twelve hours by this patient produced such relief and such feeling of well-being that she increased the dosage without obtaining further advice. It is possible that the medicament may have affected her judgment. Attention should also be called to the likelihood that some patients are more prone than others to the side effects of this drug; when it is prescribed smaller doses than those usually recommended should be used.

MULTIPLE PYOGENIC ABSCESSES OF THE LIVER

Cure by Penicillin in Case Due to Anaerobic Streptococci

MARSHALL L. MICHEL Jr., M.D.
and
WILLARD R. WIRTH, M.D.
New Orleans

Abscesses of the liver may be classified in two main groups, (1) amebic (tropical) and (2) pyogenic. Amebic hepatitis is the result of invasion of the biliary radicles by Endameba histolytica. The amebas are usually present in the large bowel and are carried through the portal veins to the liver, where a specific hepatitis occurs. Further discussion of this type of hepatic abscess is not in the scope of this paper.

Hepatitis or hepatic abscesses due to pyogenic microorganisms present a more complex clinical picture. Invasion of the liver may occur by any of four routes:[1] (1) infection from areas drained by the portal system; (2) direct spread from contiguous structures; (3) penetrating trauma, and (4) bloodborne infection. In many instances no antecedent focus of infection can be demonstrated.

A great deal has been written on pyogenic hepatic abscesses, but detailed bacteriologic studies have been neglected. In an extensive review of the literature by Ochsner[1] there were only 184 cases in which bacteriologic studies had been made. The bacteria most commonly found in pyogenic abscesses of the liver are Escherichia coli, hemolytic and nonhemolytic streptococci and staphylococci.

Many other types of pyogenic bacteria have been cultured from hepatic abscesses. Among these are Klebsiella pneumoniae, Clostridium welchi, streptococci of the viridans group, pneumococci, Alcaligenes fecalis, Bacillus subtilis, diphtheroids, Proteus vulgaris, spirochetes, Bacillus pyocyaneus, Eberthella typhosa, Bacteroides funduliformis and Bacterium dysenteriae.

Anaerobic bacteria have been infrequently reported in pyogenic abscesses of the liver, undoubtedly because of failure to obtain anaerobic cultures in a large percentage of cases. Anaerobic bacteria of various types are common inhabitants of the gastrointestinal tract. They play an important part in the etiology of numerous cases of pyogenic hepatitis.

Emphasis has been placed on the anaerobic streptococcus as a pathogenic bacteria by Meleney[2] and others. It is thought to be one of the organisms which contributes to the characteristic fecal odor of the contents of the lower portion of the small intestine and the colon. Pure cultures have been infrequently isolated from pyogenic abscesses of the liver.

In 1937 McDonald, Henthorne and Thompson[3] reported a case of perforated duodenal ulcer which was repaired surgically. Two and one half months later at necropsy multiple hepatic abscesses and a subphrenic abscess were found, from which a pure culture of anaerobic streptococci was obtained.

In 1942 St. John, Pulaski and Ferrer[4] reported an isolated abscess of the right lobe of the liver which was cured by two stage transperitoneal surgical drainage. They obtained a pure culture of anaerobic streptococci the portal of entry of which could not be definitely determined.

To our knowledge these are the only previously reported cases of pyogenic abscesses of the liver due to anaerobic streptococci.

A case is herein reported of multiple abscesses of the right lobe of the liver from which pure cultures of anaerobic streptococci were obtained at operation. The portal of entry could not be determined but the gross appearance of the liver suggested a hematogenous origin. Subsequent treatment with penicillin produced a cure. Therefore, this is the first recorded case of multiple hepatic abscesses due to anaerobic streptococci in which the patient has survived.

REPORT OF CASE

History.—B. H., a white woman aged 22, was admitted to Touro Infirmary on Oct. 19, 1943. For five weeks she had had a high fever and chills. At the onset of her illness, the patient stated she had slight abdominal pain in the region of the umbilicus, nausea and anorexia. Several days later she began to have slight pains in the right upper quadrant and epigastric region of the abdomen. This continued and the chills and fever persisted. The family history was noncontributory.

Past Medical History.—The patient stated that she had had a gynecologic disturbance several weeks prior to the onset of her present illness but refused to give any of the details. There was some question whether she might have had a miscarriage in the past several months. Otherwise, the past medical history was noncontributory.

Physical Examination.—The blood pressure was 124 systolic and 88 diastolic. The pulse rate was 130, the temperature 101 F., the respiratory rate 16. The patient was a fairly well developed, poorly nourished white woman who was acutely ill. The heart and lungs were essentially normal. In the abdomen there was decided tenderness and rigidity in the epigastrium and upper right quadrant. The spleen could be palpated approximately one fingerbreadth below the costal margin. Distention or loss of symmetry was not present. Tumor masses could not be palpated. The pelvic examination revealed normal conditions.

Laboratory Data.—There were 10,160 white blood cells and 2,760,000 red blood cells with 54 per cent hemoglobin. The differential count showed 76 per cent neutrophils, 16 per cent lymphocytes and 8 per cent monocytes. Malarial parasites were not seen in the blood. The nonprotein nitrogen level was 23 mg., the blood dextrose 97.5 mg. per hundred cubic centimeters. Urinalysis of a catheterized specimen was negative. The Wassermann test was negative, as were agglutination tests for febrile diseases, blood culture and stool examination. The serum proteins were 5.81, 7.14 and 7.07 Gm. per hundred cubic centimeters on November 15, 19 and 22, respectively.

SUMMARY

Although there is no absolute evidence that the patient whose case is herein reported took 2 000 mg of Benadryl in forty-eight hours, her general condition indicated overdosage and illustrates the danger of self medication with this drug It is of further interest that two 50 mg tablets taken in twelve hours by this patient produced such relief and such feeling of well-being that she increased the dosage without obtaining further advice It is possible that the medicament may have affected her judgment Attention should also be called to the likelihood that some patients are more prone than others to the side effects of this drug, when it is prescribed smaller doses than those usually recommended should be used

---

MULTIPLE PYOGENIC ABSCESSES OF THE LIVER

Cure by Penicillin in Case Due to Anaerobic Streptococci

MARSHALL L MICHEL Jr, M D
and
WILLARD R WIRTH, M D
New Orleans

Abscesses of the liver may be classified in two main groups, (1) amebic (tropical) and (2) pyogenic Amebic hepatitis is the result of invasion of the biliary radicles by Endameba histolytica The amebas are usually present in the large bowel and are carried through the portal veins to the liver, where a specific hepatitis occurs Further discussion of this type of hepatic abscess is not in the scope of this paper

Hepatitis or hepatic abscesses due to pyogenic micro-organisms present a more complex clinical picture Invasion of the liver may occur by any of four routes [1] (1) infection from areas drained by the portal system, (2) direct spread from contiguous structures, (3) penetrating trauma and (4) blood-borne infection In many instances no antecedent focus of infection can be demonstrated

A great deal has been written on pyogenic hepatic abscesses, but detailed bacteriologic studies have been neglected In an extensive review of the literature by Ochsner [1] there were only 184 cases in which bacteriologic studies had been made The bacteria most commonly found in pyogenic abscesses of the liver are Escherichia coli hemolytic and nonhemolytic streptococci and staphylococci

Many other types of pyogenic bacteria have been cultured from hepatic abscesses Among these are Klebsiella pneumoniae, Clostridium welchii, streptococci of the viridans group, pneumococci Alcaligenes fecalis Bacillus subtilis, diphtheroids Proteus vulgaris spirochetes, Bacillus pyocyaneus, Eberthella typhosa, Bacteroides funduliformis and Bacterium dysenteriae

Anaerobic bacteria have been infrequently reported in pyogenic abscesses of the liver, undoubtedly because of failure to obtain anaerobic cultures in a large percentage of cases. Anaerobic bacteria of various types are common inhabitants of the gastrointestinal tract They play an important part in the etiology of numerous cases of pyogenic hepatitis

Emphasis has been placed on the anaerobic streptococcus as a pathogenic bacteria by Meleney [2] and others It is thought to be one of the organisms which contributes to the characteristic fecal odor of the contents of the lower portion of the small intestine and the colon Pure cultures have been infrequently isolated from pyogenic abscesses of the liver

In 1937 McDonald, Henthorne and Thompson [3] reported a case of perforated duodenal ulcer which was repaired surgically Two and one half months later at necropsy multiple hepatic abscesses and a subphrenic abscess were found, from which a pure culture of anaerobic streptococci was obtained

In 1942 St John, Pulaski and Ferrer [4] reported an isolated abscess of the right lobe of the liver which was cured by two stage transperitoneal surgical drainage They obtained a pure culture of anaerobic streptococci the portal of entry of which could not be definitely determined

To our knowledge these are the only previously reported cases of pyogenic abscesses of the liver due to anaerobic streptococci

A case is herein reported of multiple abscesses of the right lobe of the liver from which pure cultures of anaerobic streptococci were obtained at operation The portal of entry could not be determined but the gross appearance of the liver suggested a hematogenous origin Subsequent treatment with penicillin produced a cure Therefore, this is the first recorded case of multiple hepatic abscesses due to anaerobic streptococci in which the patient has survived

REPORT OF CASE

History—B H, a white woman aged 22, was admitted to Touro Infirmary on Oct 19, 1943 For five weeks she had had a high fever and chills At the onset of her illness, the patient stated she had slight abdominal pain in the region of the umbilicus, nausea and anorexia Several days later she began to have slight pains in the right upper quadrant and epigastric region of the abdomen This continued and the chills and fever persisted The family history was noncontributory.

Past Medical History—The patient stated that she had had a gynecologic disturbance several weeks prior to the onset of her present illness but refused to give any of the details There was some question whether she might have had a miscarriage in the past several months Otherwise, the past medical history was noncontributory

Physical Examination—The blood pressure was 124 systolic and 88 diastolic The pulse rate was 130, the temperature 101 F, the respiratory rate 16 The patient was a fairly well developed, poorly nourished white woman who was acutely ill. The heart and lungs were essentially normal In the abdomen there was decided tenderness and rigidity in the epigastrium and upper right quadrant The spleen could be palpated approximately one fingerbreadth below the costal margin Distention or loss of symmetry was not present Tumor masses could not be palpated The pelvic examination revealed normal conditions

Laboratory Data—There were 10,160 white blood cells and 2,760,000 red blood cells with 54 per cent hemoglobin The differential count showed 76 per cent neutrophils, 16 per cent lymphocytes and 8 per cent monocytes Malarial parasites were not seen in the blood The nonprotein nitrogen level was 23 mg, the blood dextrose 97 5 mg per hundred cubic centimeters Urinalysis of a catheterized specimen was negative The Wassermann test was negative, as were agglutination tests for febrile diseases, blood culture and stool examination The serum proteins were 5 81, 7 14 and 7 07 Gm per hundred cubic centimeters on November 15, 19 and 22, respectively.

[4] St John, F B Pulaski E and Ferrer J M Primary Abscess of Liver Due to Anaerobic Non Hemolytic Streptococcus, Ann Surg **116**: 217 222 (Aug) 1942

Course.—The patient's temperature ran a typical septic curve. It ranged between a maximum of 104 to 105 F. and a minimum of 99 to 100 F. There was a daily elevation and decline to these levels with chills occurring when the peak was reached. This continued for two and a half weeks. The patient received extensive sulfathiazole and sulfadiazine therapy without improvement.

She was seen in consultation by a urologist, who stated that pathologic conditions were not present in the genitourinary tract. She was given frequent transfusions of blood and supportive therapy. Prior to admission she had had an extensive course of quinine and quinacrine hydrochloride without effect.

Roentgenologic Observations.—Examination of the chest revealed entirely normal conditions, and the diaphragms on both sides were smooth and well rounded. The costophrenic and cardiophrenic angles were well defined.

Anteroposterior projections of the abdomen showed the renal shadows partially obscured by intestine. However, the psoas borders were sharp and urinary or biliary calculi were not visible. The spleen was slightly enlarged. Repeated examinations of the chest revealed normal conditions.

The gastrointestinal series, with particular attention to the stomach and duodenum, also failed to reveal abnormality. Repeated examinations of the diaphragm, both by fluoroscopy and film, did not show definite abnormality.

It was concluded that the patient had a pyogenic abscess of the liver and that an exploratory laparotomy was justified.

Surgical Data.—On Nov. 2, 1943 a celiotomy was performed. Under general anesthesia, an upper right paramedian muscle-splitting incision was made. The peritoneal cavity was opened, and the liver was found to be greatly enlarged throughout all portions. There was no gross evidence of any localized abscess. Exploratory aspiration of the right lobe of the liver was performed, and a small amount of pus was obtained from several locations. The left lobe presented a similar external appearance but was not explored.

The appendix was removed because of the possibility that it was an etiologic factor. Exploration of the pelvis was negative. The original abdominal incision was closed.

A small subcostal incision was made directly over the right lobe of the liver, and the wound was packed open with iodoform gauze.

On Nov. 5, 1943, under general anesthesia, the original pack was removed. Again the right lobe of the liver was aspirated and small amounts of pus were obtained from several areas. An incision approximately 3 inches (7.6 cm.) long was made into the right lobe of the liver and was deepened with the electrosurgical unit. Inspection of the liver parenchyma revealed the presence of innumerable small abscess cavities throughout the entire substance of the right lobe. Since it was impossible to drain all these cavities surgically, the original wound in the liver was packed open with iodoform gauze.

The substance removed from the abscess was proved to be pus on microscopic examination, and pure cultures of anaerobic streptococci were obtained.

Postoperative Course.—Extensive intravenous sulfadiazine therapy from Nov. 3 to 15, 1943 was without avail. The patient continued in extremely critical condition, and the temperature was unaltered by the surgical intervention.

On Nov. 15, 1943, through the courtesy of Dr. Chester Keefer of the National Research Council, penicillin was obtained. In twenty-four hours 120,000 units of penicillin were administered intravenously. Subsequently, the dosage was gradually diminished and was administered intramuscularly. Penicillin therapy was continued for thirteen days.

Twenty-four hours after the administration of penicillin the temperature began gradually to decline. Four days after the drug was started, the temperature was down to 99.2 F. and remained between 99 and 100 F. for six days. The patient was discharged from the hospital on Dec. 2, 1943. There was still some drainage from the wound, but she was clinically much improved.

The cephalin flocculation time was 4 plus immediately before and after the operation and was also 4 plus when the patient was discharged from the hospital. The results of this test for liver function remained 4 plus for seven months.

When the patient was seen again some twenty months after the operation the cephalin flocculation time was 2 plus in twenty-four hours. The patient was completely well and did not show residual signs of her previous severe illness. When last seen she was approximately five months pregnant, and her general physical condition was excellent.

COMMENT

In the case herein reported surgical drainage and sulfonamide therapy were of no avail. The patient was completely cured by penicillin therapy. This is the first recorded case of multiple abscesses of the liver due to anaerobic streptococci in which the patient has survived. Surgical exploration was necessary in order to identify the micro-organism infecting the liver. At the time when this patient was being treated penicillin was obtainable only in limited quantities, and it was necessary to know the exact type of pathogenic bacteria involved before the drug could be obtained from the National Research Council.

At the present time and in the future pyogenic hepatitis due to anaerobic streptococci will undoubtedly be cured by the use of penicillin without first determining the exact nature of the hepatic infection by surgical exploration.

SUMMARY

1. Anaerobic bacteria have been reported infrequently as the primary etiologic factor in pyogenic abscesses of the liver.
2. Two previous cases of hepatic abscess due to anaerobic streptococci have been reported. One of these was a single abscess which was cured surgically. The other case showed multiple abscesses and had a fatal termination.
3. Herein is reported the third recorded case of hepatic abscess due to anaerobic streptococci. Multiple abscesses were present, and the patient was cured with penicillin after surgical drainage and sulfonamide therapy had been ineffective.
4. This is the first recorded case of multiple abscesses of the liver due to anaerobic streptococci which has been cured.
5. In the future, cases of pyogenic hepatitis due to anaerobic streptococci will undoubtedly be cured by penicillin without surgical drainage to determine the exact bacteriologic cause of the hepatic infection.
6. Penicillin is an effective agent against anaerobic streptococci.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article.

The Council wishes to express its appreciation for the valuable cooperation of the Consultants on Audiometers and Hearing Aids in reviewing this article. The consultants are Dr. William E. Grove, chairman, and Drs. Gordon Berry, Hallowell Davis, Edmund P. Fowler, Isaac H. Jones, Dean Lierle, Moses H. Lurie, Douglas Macfarlan, C. Stewart Nash and Paul E. Sabine. Howard A. Carter, *Secretary.*

TENTATIVE STANDARD PROCEDURE FOR EVALUATING THE PERCENTAGE LOSS OF HEARING IN MEDICOLEGAL CASES

1. Since the pure tone audiometer is the best available instrument for determining the acuity of hearing, the procedure recommended herein is based on measurements of hearing loss with an accepted standard audiometer. Since, in the present state of knowledge, it is not possible to arrive at quantitative evaluation of hearing capacity except by audiometric measurements, no consideration is given to other than audiometric data in setting up this basic procedure.

2. The recommended procedure is based only on threshold measurements of acuity of hearing for air-conducted sound.

3. Under each frequency, the weighted percentage losses corresponding to measured decibel losses are shown on the charts before they are filled out. These percentages are based on the existing data bearing on the relative importance of the different portions of the auditory frequency and intensity range in the hearing of speech.

4. To determine the percentage of hearing loss with the charts, proceed as shown in the instructions beneath them.

5. Computation of binaural hearing loss is carried out in four steps indicated under the heading, "Computation of per cent loss of capacity to hear speech." The weighting of percentage losses shown for the two ears represents the composite judgment of the Consultants on Audiometers and Hearing Aids. This judgment is based on both clinical experience and practical considerations. The percentage loss of hearing is the average of the losses for the better ear and for the poorer ear taken separately and weighted in the ratio of 7 to 1.

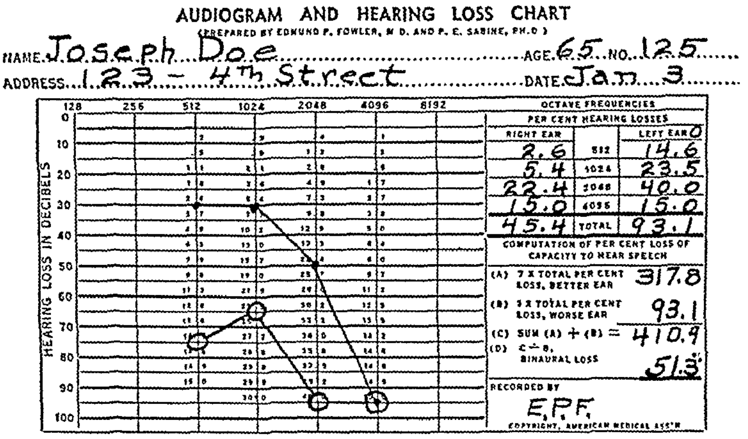
The percentages that are shown on the charts were arrived at from quantitative data to be found in selected references.[1]

The foregoing is recommended as a tentative standard procedure based on present knowledge of the relation between the audiometrically measured acuity of hearing and the capacity to hear direct speech in a familiar language.

This procedure is subject to revision when further authoritative data on the problem become available.

SAMPLE PROBLEM

Assuming that the physician is fully acquainted with the technic of measuring the decibel loss of hearing by means of an accepted audiometer, points are plotted as shown in charts 1 and 2.



AUDIOGRAM AND HEARING LOSS CHART

Set down these figures in the four spaces under right and left ear, in the columns to the right of the chart. Add each column and compute the binaural per cent loss of capacity to hear speech, as indicated.

Chart 2.—Sample audiogram chart.

The charts illustrate two differing symbols for plotting the right ear, chart 1 using the dot (.), and chart 2 using the x.

HISTORICAL NOTE

In 1938 the lack of uniformity in the methods that were employed for estimating the percentage loss of hearing for speech, as pointed out by courts of law, insurance companies, compensation courts and others, caused the Consultants on Audiometers and Hearing Aids of the Council on Physical Medicine to formulate a method for the consideration of otologists and physicians.

The House of Delegates at its annual meeting in 1939 approved the action of the Consultants for the standardization of tests and the preparation of a method for estimating the percentage loss of hearing.

The method was indorsed by the Consultants and was adopted by the Council on Physical Medicine and the Section on Laryngology, Otology and Rhinology at the annual session of the American Medical Association in 1942 and by the House of Delegates at its annual meeting in Atlantic City in June 1942. At the time at which the procedure was compiled and adopted the Consultants on Audiometers and Hearing Aids were C. D. Bunch (deceased), George M. Coates, Edmund P. Fowler, W. E. Grove, Isaac H. Jones, W. MacFarland, C. Stewart Nash, Horace Newhart (deceased), Paul E. Sabine and W. E. Wheery (deceased).

A description of the procedure was first published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Aug. 1, 1942, volume 119, pages 1108 and 1109.

At the time when the method was compiled the Consultants realized that it might require readjustment. Therefore specialists in otology were encouraged to try the procedure in the course of their regular office practice and compare the resultant calculations with whatever additional information might come to their attention. In short, physicians were asked to give the procedure a practical test. Certain shortcomings were reported, and in 1943 and 1944 the Consultants reviewed their work and recommended certain revisions. Comparison of the revised chart with the former one will indicate that the revised chart is simpler to use and requires less arithmetic to arrive at the per cent of loss of hearing. For equal binaural losses, the percentage figures correspond closely with those used in Dr. Fowler's method. The major part of the work in connection with the revision of the chart was performed by Dr. E. P. Fowler and Dr. Paul E. Sabine. At present the members of the Consultants on Audiometers and Hearing Aids are Drs. Gordon Berry, Hallowell Davis, E. P. Fowler, W. E. Grove, Isaac H. Jones, Dean Lierle, Moses H. Lurie, Douglas Macfarlan, C. Stewart Nash and Paul E. Sabine.

SATURDAY, FEBRUARY 8, 1947

DEPARTMENT OF HEALTH, EDUCATION AND SECURITY

A brief editorial reference was made in THE JOURNAL January 18 to pending legislation in Congress, introduced by Senator Fulbright and Senator Taft as S. 140, to create an executive department of the government to be known as the Department of Health, Education and Security. A similar bill is pending in the House, H. R. 573, introduced by Representative Harris, Arkansas. This proposal is of much importance to American medicine.

At the head of the new department would be a Secretary of Health, Education and Security appointed by the President by and with the advice and consent of the Senate. The qualifications to be possessed by the Secretary are not stated. In the department there would be three main divisions, each under the immediate supervision of an Under Secretary, a Division of Health, a Division of Education and a Division of Security. The Under Secretary of Health would be a doctor of medicine licensed to practice medicine or surgery in one of the states or territories of the United States or in the District of Columbia, and would perform "such duties concerning health as may be prescribed by the Secretary or required by law." Thus, apparently, the duties of the Under Secretary of Health, who must be a doctor of medicine, will in part be prescribed by the secretary of the department, whose qualifications are not set forth in the bill. Too, one section of the bill would authorize the secretary to delegate to any officer, board or employee of the department any of his functions, powers and duties except that the function of promulgating or approving regulations may be delegated only to an under secretary. Presumably this authority to delegate functions includes the right to delegate the prescribing of the duties to be performed by the Under Secretary of Health.

Provision is made for the appointing by the secretary of advisory committees to advise and consult with him, the membership of which must include such persons not otherwise employed by the federal government as in his judgment are most representative of voluntary organizations operating in the respective fields with relation to which such committees may be appointed.

Generally stated, the new department would be authorized to promote the general welfare by aiding and fostering programs in the field of health, education and security, and related services contributing to individual, family and community well-being. These objectives would be carried out, it is contemplated, to the "fullest possible extent through state and local agencies, public and voluntary, and in such manner as to preserve and protect to the highest possible degree the independence and autonomy of state and local agencies, public and voluntary, in education, health, security and related fields."

Specifically, the department would be authorized to—

(*a*) aid, stimulate and encourage the development throughout the nation of services and facilities, both public and voluntary, in the fields of health, education, security and related fields;

(*b*) promote, foster and encourage state, community and voluntary activity in those fields;

(*c*) advise and cooperate with other departments and agencies of the federal government, with state governments and agencies and with voluntary agencies functioning in those fields;

(*d*) collect and analyze statistics and make studies, investigations and reports on conditions, problems and needs in those fields in the United States and in other countries, and disseminate and make available information in those fields;

(*e*) make reports and recommendations with respect to the most effective policies and methods for the promotion of health, education, security and related services, including recommendations with respect to legislation and matters of administrative policy;

(*f*) advise and cooperate with international organizations functioning in those fields; and

(*g*) administer such federal programs, including grants-in-aid, and such powers, functions and duties in those fields as are assigned to it or provided through this or subsequent legislative enactment.

The office of the federal security administrator and the Federal Security Agency, and its constituent units, together with all their functions, would be transferred to the department and, subject to the exceptions noted, would be allocated, distributed and administered under the direction and supervision of the secretary, who would be authorized to abolish such office and agency and any such unit in the interest of administrative efficiency.

To the Division of Health would be specifically transferred the U. S. Public Health Service, the Freedmen's Hospital, the Food and Drug Administration and the Federal Board of Hospitalization. To the Division of Security, the under secretary of which will be a person experienced in the field of social security and welfare, will be transferred the Committee on Economic Security and the Children's Bureau. The Office of Education and the functions of the Federal Security Agency relating to the administration of Howard University and the Columbia Institution for the Deaf will be transferred to the Division of Education.

Essentially, it would seem that the effect of this legislation would be to transform the Federal Security Agency with its various and not too closely related functions into an executive department with a relocation of the several functions of that agency. While the House of Delegates has repeatedly urged that a national department of health be established, it has recognized the dangers incident to the mingling in one department of health and other functions. At a special meeting held in 1937 at a time when the reorganization of governmental activities in the executive departments was under consideration, the Board of Trustees prepared a statement expressing the opinion that "health activities of the government, except those concerned with the military establishments, should not be subservient to any other departmental interests." This action of the Board of Trustees was approved by the House of Delegates at its meeting in Atlantic City in June 1937.

The pending bill, if enacted, might serve to bring about such subserviency; its consideration by the Congress will demand close attention by the medical profession.

THE "PERSONAL EQUATION" IN THE INTERPRETATION OF A CHEST ROENTGENOGRAM

In 1944 the Veterans Administration instituted a study of the effectiveness of roentgenologic methods for tuberculosis case finding. Attempts to evaluate the relative efficiency of various sizes of film demonstrated that there is considerable inconsistency of interpretation of chest roentgenograms among expert radiologists and chest specialists. Indeed, not one of the observers was consistent with himself when he interpreted a second time the same films on which he had originally made supposedly final observations.

The Veterans Administration, faced with the problem of filing and evaluating millions of chest films of veterans, appointed this Board of Roentgenology to evaluate the diagnostic efficiency of the various sizes of film which had been used by the armed forces. This board, whose results are published in this issue of THE JOURNAL,[1] was composed of two radiologists and three chest specialists of repute. Assisting these men in the statistical aspects of their work was a medical statistician of the U. S. Public Health Service. Because of the thoroughness and integrity of this prolonged investigation, the conclusions of the research merit close scrutiny and indicate the desirability of similar future studies.

In the course of this study 1,200 conventional 14 by 17 inch celluloid films were available. The five readers read all the films independently, and their results were tabulated. At a later date each reader interpreted the same films again.

The interindividual variation, or the failure of an individual reader to be consistent with other readers, had great magnitude. For example, on reading the 14 by 17 inch films, one reader called 59 films "positive"; another reader called 31 per cent of these 59 films "negative"; another found 29 per cent of the 59 "negative," and still another found 14 per cent "negative."

The intraindividual variation, or the failure of a reader to be consistent with himself in two independent readings, is even more astonishing. One reader found 59 films "positive" on the first reading of 14 by 17 inch celluloid films, and on the second reading of the same films he found as many as 78 "positives," and these did not include all of his original 59 "positives."

Apprised of these observations, other radiologists and chest specialists, believing that their interpretations would not reveal such discrepancy, undertook smaller scale studies of these films. The error of these incidental trials was as great as and in many instances greater than that encountered in the original research.

These discrepancies demand serious consideration. Further refinements and details are available in the article itself. Error resulting from the "personal equation" exists in all fields of knowledge; but it is only in those in which the evidence is measurable that its magnitude has been demonstrated. Probably in fields in which the evidence cannot be measured the occurrence of error will be at least as frequent as it is in radiology. Indeed, significant studies have shown the limitations of human perception. Such researches as those of Yule,[2] Pearson,[3] Berkson, Magath and Hurn [4] and Derryberry [5] expose discrepancies as astonishing as those here reported of roentgenology. It was shown that in many objective activities, such as the judgment of the most simple characteristics of hybrid corn, estimate of blood cell count, and the determination of malnutrition in children, dependable consistency of judgment was not present.

Reflection and memory restore our confidence. There has been a tendency to assume that roentgenology is an exact science and that the objectivity of the medium defied error. Complacency has been a consequence of such assumption.

Conditions *inherent in the* x-ray *image* tend to minimize the shock to confidence of these results.

Every x-ray shadow represents a projection on a two dimensional surface of an accumulation of details in a three dimensional object. Such a spatial condition must necessarily make for distortions that will confuse appearance and reality and, in eliminating the depth factor, diffuse observable foci.

Then again it must be remembered that, in spite of the limitations enforced on roentgenologic diagnosis by the "personal equation," almost all gross pathologic change is visualized by the roentgenogram and does not escape the scrutiny of the competent observer. Indeed, long experience has shown that in diseases of the chest the roentgenogram finds the significant cases and serves as the principal tool of diagnosis.

There is courage of a unique order in this self examination of professional conscience and competence. What other profession, trade or business submits itself voluntarily to such analysis? The experiment has encouraged the drive toward perfection and hastened progress!

RESEARCH AND MEDICAL PROGRESS

In a recent address Goodpasture[1] indicates that financial support of research has come heretofore largely from universities, philanthropic foundations, industry and government. Available funds from the first two sources are no longer adequate to meet increasing demands. Their inadequacy is reflected in a tendency to support short term projects of developmental character rather than of fundamental nature. Great risk and unavoidable financial waste are associated with exploratory research. Industry has profited greatly from the results of fundamental research but has not devised means of affording a commensurate free financial aid to universities, except for that granted by certain individual philanthropic industrialists.

The need is great for free and fluid funds in sufficient quantity to support advanced training so that the risks of original fundamental research may be taken as needed. The only support of this magnitude visible today is public or government funds. Support from this source, however, might encounter difficulties in the selection of projects and be subject to political interests. Goodpasture contends that the privilege and responsibility of determining the trends of research, the training of scientists and the extent and quality of the result should rest with the university faculty. They should be able to take the scientific risks and meet the cost of any waste. Public funds can meet this need not only by grants-in-aid for definite research but also by grants to the faculties, to be spent at their own discretion.

Medicine, Goodpasture emphasizes, is dedicated to the service of man and not to a social order. "Let each social order therefore give the scientist a free hand," he pleads, "and provide him with the environment and the tools he needs; make him accessible to students, for he is essentially a teacher; make the university his home; and otherwise, for humanity's sake, leave him alone."

Medical science and social reorientation have greatly influenced the environment of the medical practitioner. Public health measures, based on bacteriology and immunology, and industrial hazards are now in the sphere of public responsibility. Problems in nutrition are rapidly coming into the same domain. As his duties take the physician from the home to the hospital ward, social agencies expand to perform some of his former tasks.

Large scale support of medical research by public funds is already in existence. Van Slyke[2] has outlined the plan of U. S. Public Health Service research grants to independent scientists. This program recognizes ". . . the integrity and independence of the research worker and his freedom from control, direction, regimentation and outside interference." A total of 264 research projects in 77 institutions, supported by $3,900,000, have been approved within its first year of operation. A definite attempt is made to support fundamental research. The program seems to meet most of the ideal standards proposed by Goodpasture, but it appears to retain some of the hazards inherent in grants-in-aid for specific projects. This program fails, moreover, to provide the free fluid funds under the control of faculties which Goodpasture advocated. Perhaps, to a certain degree, the scientists who constitute the membership of the national advisory councils and the study sections may be regarded as the faculties.

Another program of government support of research is that outlined by Powers.[3] Through its office of naval research the Navy Department subsidizes basic research on a large scale in university and industrial laboratories. The War Department does likewise through various organizations. The funds available for research for this year are about $70,000,000 for each service. Some of these federal funds are devoted to medical research. These research organizations were begun in 1946 at a time when there was lack of agreement among scientists as to the best form and function of a National Science Foundation. No doubt the present Congress will take additional steps toward establishing a National Science Foundation.

Thus 1946 witnessed a great expansion of federal subsidy of medical research. The full impact of this program is not yet felt. One deficiency in the overall program may be inadequate opportunities for training young scientists. The effects of the federal support of projects on the quality of university faculties will be observed with great interest. How well the present programs strike a balance between support of basic, fundamental research and developmental research should be revealed soon.

RETIREMENT OF CIVILIAN OFFICERS OF THE ARMY

Last year both the Reserve Officers Association and the National Guard Association criticized the machinery of retirement of army officers, claiming discrimination against the civilians who had served with the Army. Resolutions were passed by both organizations charging unfairness and favoritism; indeed, charges were made that laws and regulations were being purposely misinterpreted.

Retirement procedure in the Army is largely a medical function. The officer to be retired is first given a physical survey in a hospital; he then appears before a disposition board, all the members except the recorder being physicians. Finally he appears before a retiring board, with at least two medical members. Medical witnesses familiar with the case are called to testify, and the board proceedings are reviewed by physicians in the War Department. Because of this method of procedure, the censure of the resolutions passed by the two associations would seem to fall on medical shoulders even if it was not so intended.

The complaints were so serious that the War Department appointed a committee to make a careful investigation. The committee was composed of officers from all components and represented various branches of the service. The results of the investigation have never been made public. It is understood, however, that the committee devoted much time to its work and made a thorough and complete investigation. The findings of the committee did not substantiate the charges made by the two organizations. The committee found, however, that medical officers, the vast majority of whom were from civilian life, were conscientious in their work and that their findings were in accord with the laws and regulations governing retirement. Errors may have been made in individual cases, but these were few and were largely matters of professional judgment and opinion.

The committee report should be made public so that even the shadow of suspicion may be removed from the medical members of the Disposition and Retiring boards. The splendid body of men who volunteered their services in the war effort certainly did not indulge in double dealing or chicanery.

Current Comment

FEDERAL INCOME TAXES

Elsewhere in this issue of The Journal (page 402) appears the annual statement prepared by the Bureau of Legal Medicine and Legislation to aid physicians in complying with the requirements of the federal income tax law. Contained in it are suggestions as to the deductibility of expenses relating specifically to the practice of medicine, such as dues to medical organizations, traveling expenses incurred in attending medical meetings and subscriptions to medical periodicals. The statement should be read carefully by physicians. According to a recent news item, income tax officials have stated that the majority of physicians do maintain accurate data and faithfully report their incomes. This item disclosed, however, that in one collection district a check of the returns filed by physicians brought to light a number of instances of faulty returns. One physician reputedly agreed to settle his indebtedness out of court, covering a period of almost ten years, for a figure said to be "nearly $1,000,000." Another volunteered to pay $92,000, representing unpaid taxes for several years, plus penalties and interest and by doing so escaped indictment by a federal grand jury.

DELETERIOUS FACTOR IN WHOLE WHEAT BREAD

Hitchens and Falco[1] of the Wellcome Research Laboratories, Tuckahoe, N. Y., showed that mice fed Purina fox chow, Rockland mouse diet or Robinson and Siegel's[2] stock diet are highly susceptible to experimental type I pneumococcus infection. In contrast, mice fed a purified synthetic diet containing all known vitamins and other essential food elements are resistant to 100,000 lethal doses of the same culture. As an explanation of this increased resistance, Hitchens assumed that the crude foodstuffs of commercial diets contain some unknown deleterious factor. This factor is presumably more beneficial to the parasitic growth of the pneumococcus than to the animal consuming the food. Their more recent study[3] concerned the deleterious effects of whole wheat bread. Preliminary tests had shown that aqueous extracts of whole wheat flour are much richer in factors stimulating the in vitro growth of the pneumococcus than control extracts of white flour. One hundred mice were therefore maintained solely on white bread or whole wheat bread for six days before injection with pneumococci. Of the 50 mice maintained on white bread, 20 (or 40 per cent) survived the experimental infection. Of the 49 mice fed exclusively on whole wheat bread, only 1 mouse (or 2 per cent) survived. Presumably there is superiority of white bread over whole wheat bread measured by comparative resistance to experimental pneumococcic infection. For general nutrition, whole wheat is considered by nutritional physiologists superior.

ORGANIZATION SECTION

THE PHYSICIAN'S FEDERAL INCOME TAX

PREPARED BY THE BUREAU OF LEGAL MEDICINE AND LEGISLATION, AMERICAN MEDICAL ASSOCIATION

Federal income taxpayers on a calendar year basis must on or before March 15 do two things: (1) they must file their final returns for the year 1946 and (2) they must file a declaration of estimated tax for 1947.

WHO MUST FILE RETURNS

A return must be filed by every citizen or resident of the United States whose total gross income in 1946 was $500 or more. Joint returns may be filed by husband and wife if (1) they were married at the end of the year and (2) both were citizens or residents of the United States. Such a joint return may be filed even though one spouse has neither income nor deductions.

WHO MUST FILE DECLARATIONS OF ESTIMATES

In addition to filing the final return for 1946, certain taxpayers must file on or before March 15 a declaration of estimated tax for 1947. Such a declaration must be filed by a taxpayer if—

(1) his gross income from wages or salary subject to withholding can reasonably be expected to exceed the sum of $5,000 plus $500 with respect to each exemption, except his own; or

(2) his gross income which is not subject to withholding can reasonably be expected to exceed $100 for 1947 and his gross income from all sources can reasonably be expected to be $500 or more.

A taxpayer, if necessary, may file one or more amended declarations during 1947 but only one in each calendar quarter. The last such amended declaration must be filed on or before Jan. 15, 1948.

The estimated tax may be payable quarterly as it was in 1946, the final payment becoming due Jan. 15, 1948.

TAX RATES AND EXEMPTIONS

The normal tax rate remains at 3 per cent but after the tentative tax is computed at this rate there is allowed a reduction of 5 per cent of the tax thus computed. The surtax rate begins at 17 per cent of the first $2,000 of surtax net income. As with the normal tax, after the tentative surtax is computed a reduction of 5 per cent of it is permitted by the Revenue Act of 1945. These rates apply in connection with 1946 income. They must also be used in the declaration of estimated tax for 1947, unless rates are changed by the Congress prior to March 15.

For both normal and surtax purposes, the exemptions are in the amount of $500 each for the taxpayer, for his or her spouse, and for each dependent whose gross income is under $500.

The determination as to whether a taxpayer is single or married is made as of the last day of the taxable year. There is no status determination date for dependents, the test being whether the taxpayer furnished over half of the support.

GROSS AND ADJUSTED GROSS INCOMES

Gross Income.—A physician's gross income is the total amount of money received by him during the year for professional services, regardless of the time when the services were rendered for which the money was paid, assuming that the return is on a cash receipts and disbursements basis, plus such money as he has received from investments and from other sources.

If a physician receives a salary as compensation for services rendered and in addition thereto living quarters or meals, the value to the physician of the quarters and meals so furnished ordinarily constitutes income subject to tax. If, however, living quarters or meals are furnished for the convenience of the employer, the value thereof need not be computed and added to the compensation otherwise received by the physician. As a general rule, the test of "convenience of the employer" is satisfied if living quarters or meals are furnished to a physician who is required to accept such quarters and meals in order to perform properly his duties. For example, if a physician employed by a hospital is subject to immediate service at any time during the twenty-four hours of the day and therefore cannot obtain quarters or meals elsewhere without material interference with his duties and on that account is required by the hospital to accept the quarters or meals furnished by it, the value thereof need not be included in the gross income of the physician.

Adjusted Gross Income.—Adjusted gross income is defined to mean gross income minus—

(1) deductions attributable to a trade or business carried on by the taxpayer, if such trade or business does not consist of the performance of services by the taxpayer as an employee;

(2) expenses of travel, meals and lodging while away from home, paid or incurred by the taxpayer in connection with the performance by him of services as an employee;

(3) certain reimbursed expenses in connection with employment;

(4) deductions attributable to property held for the production of rents or royalties;

(5) depreciation or depletion allowed a life tenant of property or to an income beneficiary of property held in trust; and

(6) losses from the sale or exchange of property.

The adjusted gross income is to be used as a basis to determine (1) the limitation on the deduction for charitable contributions (15 per cent of the adjusted gross income), (2) the amount of the deduction for medical expense (excess over 5 per cent of adjusted gross income), (3) the amount of the optional standard deduction the taxpayer may elect to take (10 per cent of adjusted gross income in certain income brackets), (4) exemptions in certain cases where joint returns are filed by husband and wife and (5) if the taxpayer may take advantage of the optional tax table devised for incomes under $5,000.

OPTIONAL TAX TABLE

If a taxpayer has an adjusted gross income of less than $5,000, he may if he so elects compute his tax by using the optional or alternative tax table. This table allows for the normal tax and surtax exemptions and for nonbusiness deductions approximating 10 per cent of the adjusted gross income. The election may be exercised irrespective of the source of the income. This table may not be used if the adjusted gross income of the taxpayer is $5,000 or more but in such cases an optional flat $500 deduction may be claimed in lieu of nonbusiness deductions generally, such as charitable contributions, interest and taxes. Such a taxpayer may elect to exercise this option or he may itemize such deductions as in prior years. The taxpayer who reports an adjusted gross income of less than $5,000 a year will not be allowed the standard deduction as a separate item. Its benefits may be obtained only by using the optional tax table, which, as already indicated, assumes that the user of the table is entitled to a deduction approximating 10 per cent of his adjusted gross income.

PHYSICIANS IN SERVICE

The fact that a physician is in service does not of itself excuse a failure to file a return or declaration. It is understood, however, that if because of the inaccessibility of the necessary records a physician in service is unable to file a complete return he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following the procedure. At a later date, if that procedure is followed, a complete return must be filed and necessary adjustments in tax will be made. What has just been said relates to physicians in service who are stationed in this country.

If a physician in service is on duty outside the United States, no income tax will become due, generally speaking, until the fifteenth day of the sixth month following the month in which the physician ceases, except by reason of death or incompetence, to be a member of the military forces on sea duty or in service outside the continental United States, or the fifteenth day of the third month following the month in which World War II is terminated, whichever may be the earlier. When a physician in service returns to the United States, he should contact his local collector of internal revenue and make arrangements to bring his returns up to date.

The law provides a special exemption for members of the armed forces. For taxable years after 1942 and before the termination of the war, so much of the active service pay as does not exceed $1,500, received as a commissioned officer or a commissioned warrant officer, is excluded from gross income. In addition, the commissioned officer is entitled to the personal exemptions, credits and allowable deductions provided by law. For taxable years after 1940 and before the end of the war all of the pay for active service received by a serviceman below the grade of commissioned officer or commissioned warrant officer is nontaxable. He too is entitled to the other exemptions, credits and deductions.

If ability to make payment is materially impaired by reason of service, deferment of the tax, without interest, until six months after active service terminates can be effected through the office of the collector of internal revenue, under section 513 of the Soldiers' and Sailors' Civil Relief Act. Furthermore, if it causes hardship to meet tax liability after termination of service, additional extension may be obtained under section 700 of that act, by application to the courts, for a period equal to the length of military service, subject to the requirement of periodic payment, with interest at 6 per cent.

The Revenue Act of 1945 grants further extension of time for payment, without interest, of any tax attributable to service pay for any taxable year beginning after Dec. 31, 1939 and before Jan. 1, 1947. The payment of the tax, if proper application is made, will be extended for thirty-six months, payable in twelve equal quarterly instalments. In the case of regular officers this extension operates only when the tax has been deferred by reason of sea or oversea duty. Application for the extension must be filed before the first instalment date which the law fixes as follows: If the release from active duty was prior to Dec. 1, 1945, the first instalment date was May 15, 1946; (2) if released on or after Dec. 1, 1945 the first instalment date will be June 15, 1947 or the fifteenth day of the sixth month which begins after the date of release from active duty, whichever is earlier. A similar extension can be had in connection with the payment of the tax attributable to earned income of the years 1940 and 1941 which became due after entry into service. Earned income for this purpose cannot exceed $14,000.

Any tax owed by a member of the military or naval forces who dies in service will be canceled, this relief being retroactive to Dec. 7, 1941. If the tax has already been assessed at the time of the death of the person in service it will be abated. If the tax has already been collected it will be refunded as overpayment. This tax forgiveness applies only to income taxes and not to the estate tax.

The cost of equipment of an army officer or navy officer is deductible only to the extent that it is especially required for his profession and does not merely take the place of articles required in civilian life. The cost of uniforms is considered a personal expense and hence not deductible. The cost of gold braid and cap devices required by regulations of the Navy to be worn on the clothing of a naval officer has been held to constitute an expense necessited by reason of his profession as an officer and to be deductible as a business expense.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equip-may not be used if the adjusted gross income of the taxpayer is $5,000 or more but in such cases an optional flat $500 deduction may be claimed in lieu of nonbusiness deductions generally, such as charitable contributions, interest and taxes. Such a taxpayer may elect to exercise this option or he may itemize such deductions as in prior years. The taxpayer who reports an adjusted gross income of less than $5,000 a year will not be allowed the standard deduction as a separate item. Its benefits may be obtained only by using the optional tax table, which, as already indicated, assumes that the user of the table is entitled to a deduction approximating 10 per cent of his adjusted gross income.

PHYSICIANS IN SERVICE

The fact that a physician is in service does not of itself excuse a failure to file a return or declaration. It is understood, however, that if because of the inaccessibility of the necessary records a physician in service is unable to file a complete return he may file a tentative return on which he must estimate his income, deductions and tax as best he can and indicate on the return his reasons for following the procedure. At a later date, if that procedure is followed, a complete return must be filed and necessary adjustments in tax will be made. What has just been said relates to physicians in service who are stationed in this country.

If a physician in service is on duty outside the United States, no income tax will become due, generally speaking, until the fifteenth day of the sixth month following the month in which the physician ceases, except by reason of death or incompetence, to be a member of the military forces on sea duty or in service outside the continental United States, or the fifteenth day of the third month following the month in which World War II is terminated, whichever may be the earlier. When a physician in service returns to the United States, he should contact his local collector of internal revenue and make arrangements to bring his returns up to date.

The law provides a special exemption for members of the armed forces. For taxable years after 1942 and before the termination of the war, so much of the active service pay as does not exceed $1,500, received as a commissioned officer or a commissioned warrant officer, is excluded from gross income. In addition, the commissioned officer is entitled to the personal exemptions, credits and allowable deductions provided by law. For taxable years after 1940 and before the end of the war all of the pay for active service received by a serviceman below the grade of commissioned officer or commissioned warrant officer is nontaxable. He too is entitled to the other exemptions, credits and deductions.

If ability to make payment is materially impaired by reason of service, deferment of the tax, without interest, until six months after active service terminates can be effected through the office of the collector of internal revenue, under section 513 of the Soldiers' and Sailors' Civil Relief Act. Furthermore, if it causes hardship to meet tax liability after termination of service, additional extension may be obtained under section 700 of that act, by application to the courts, for a period equal to the length of military service, subject to the requirement of periodic payment, with interest at 6 per cent.

The Revenue Act of 1945 grants further extension of time for payment, without interest, of any tax attributable to service pay for any taxable year beginning after Dec. 31, 1939 and before Jan. 1, 1947. The payment of the tax, if proper application is made, will be extended for thirty-six months, payable in twelve equal quarterly instalments. In the case of regular officers this extension operates only when the tax has been deferred by reason of sea or oversea duty. Application for the extension must be filed before the first instalment date which the law fixes as follows: If the release from active duty was prior to Dec. 1, 1945, the first instalment date was May 15, 1946; (2) if released on or after Dec. 1, 1945 the first instalment date will be June 15, 1947 or the fifteenth day of the sixth month which begins after the date of release from active duty, whichever is earlier. A similar extension can be had in connection with the payment of the tax attributable to earned income of the years 1940 and 1941 which became due after entry into service. Earned income for this purpose cannot exceed $14,000.

Any tax owed by a member of the military or naval forces who dies in service will be canceled, this relief being retroactive to Dec. 7, 1941. If the tax has already been assessed at the time of the death of the person in service it will be abated. If the tax has already been collected it will be refunded as overpayment. This tax forgiveness applies only to income taxes and not to the estate tax.

The cost of equipment of an army officer or navy officer is deductible only to the extent that it is especially required for his profession and does not merely take the place of articles required in civilian life. The cost of uniforms is considered a personal expense and hence not deductible. The cost of gold braid and cap devices required by regulations of the Navy to be worn on the clothing of a naval officer has been held to constitute an expense necessited by reason of his profession as an officer and to be deductible as a business expense.

DEDUCTIONS FOR PROFESSIONAL EXPENSES

A physician is entitled to deduct all current expenses necessary in carrying on his practice. The taxpayer should make no claim for the deduction of expenses unless he is prepared to prove the expenditure by competent evidence. So far as practicable, accurate itemized records should be kept of expenses and substantiating evidence should be carefully preserved. The following statement shows what such deductible expenses are and how they are to be computed:

Office Rent.—Office rent is deductible. If a physician rents an office for professional purposes alone, the entire rent may be deducted. If he rents a building or apartment for use as a residence as well as for office purposes, he may deduct a part of the rental fairly proportionate to the amount of space used for professional purposes. If the physician occasionally sees a patient in such dwelling house or apartment, he may not, however, deduct any part of the rent of such house or apartment as professional expense; to entitle him to such a deduction he must have an office there, with regular office hours. If a physician owns the building in which his office is located, he cannot charge himself with "rent" and deduct the amount so charged.

Office Maintenance.—Expenditures for office maintenance, as for heating, lighting, telephone service and the services of attendants, are deductible.

Supplies.—Payments for supplies for professional use are deductible. Supplies may be fairly described as articles consumed in the using; for instance, dressings, clinical thermometers, drugs and chemicals. Professional journals may be classified as supplies and the subscription price deducted. Amounts currently expended for books, furniture and professional instruments and equip-

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts expended for medical, dental and hospital care for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the adjusted gross income of the taxpayer but not in excess of $2,500 in case of a taxpayer with more than one exemption, or $1,250 in case of a taxpayer with only one exemption.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold.

Washington Letter

(From a Special Correspondent)

Feb. 5, 1947.

Training of Six Hundred in Psychiatric Work Advocated by Mental Health Council

The National Advisory Mental Health Council, meeting here, has approved the training this year of six hundred psychiatric personnel, including one hundred and fifty psychiatrists and the same number in the related fields of psychology, psychiatric social work and nursing. The program was adopted to meet a national shortage of psychiatric personnel. Dr. Edward A. Strecker of Philadelphia, head of the council's training committee, said that the figure seemed inadequate in view of his estimate that "we have less than one third of the psychiatrists needed to meet the minimum psychiatric needs of the country."

Federal Officials Puzzled by Large United States Consumption of Sleeping Pills

Government officials are reported to be puzzled by the heavy consumption of sleep-producing barbiturate drugs each year. Experts say that the 1945 production of 582,000 pounds was enough to put every American man, woman and child to sleep each night for two weeks. The pharmaceutical and drug industry, represented by the National Drug Trade Council, is campaigning for stronger controls and has sponsored a model law before state legislatures. Representative Rogers of Massachusetts has introduced a bill in Congress to place barbiturate compounds under the Federal Narcotics Act.

Delays in Providing Hospitalization for Veterans

Representative Rogers of Massachusetts has announced that the House Veterans Committee, of which she is chairman, will investigate the adequacy of hospitals operated by the Veterans Administration. A subcommittee, headed by Representative Kearney, New York Republican, will check on complaints that former servicemen are required to wait too long for hospitalization. Mrs. Rogers declares that an acute shortage of hospital beds for women veterans exists, despite repeated requests for more. She stated: "We set aside 500 million dollars for veterans' medical research and care three years ago when we passed the GI bill of rights, and I'd like to see that program taking shape."

Convictions Against Eight Limb Manufacturers Reversed by Court

The United States Court of Appeals has reversed antitrust convictions which were handed down in district court last May against eight artificial limb manufacturers. The five corporations and three individuals involved in the reversal were among eighty indicted for conspiracy to fix the price of artificial limbs in violation of the Sherman Anti-Trust Act. The court based its reversal on "an abuse of discretion" by the trial judge. Sixty-three of the accused had entered pleas of nolo contendere (no contest). Those winning reversals were J. E. Hanger, Inc., of Washington, D. C.; separate corporations of the same name in Illinois, Indiana, Missouri and Texas; Joseph F. Branham, vice president of the Illinois firm; McCarthy Hanger, president of the Missouri corporation, and Hugh H. Hanger, who operates a separate business in Philadelphia.

Outlines Work of World Health Organization

The World Health Organization was created to elevate the physical and mental health of all people, Dr. Frank A. Calderone, director of the headquarters office of the interim group, told delegates to the twenty-first Women's Patriotic Conference on National Defense. He said sixty-one nations had given enthusiastic support to the organization.

National Birth Rate Shows Increase

The U. S. Public Health Service has estimated the number of births registered for the first eleven months of 1946 to 2,922,000, 16 per cent above the 1945 figure. A small increase in deaths was recorded in the same period, the estimated 1,275,000 being 16,000, or 1.3 per cent, more than in 1945 ment, "the useful life of which is short," generally less than one year, may be deducted, but if such articles have a more or less permanent value, their purchase price is a capital expenditure and is not deductible.

Equipment.—Equipment comprises property of a more or less permanent nature. It may ultimately wear out, deteriorate or become obsolete, but it is not in the ordinary sense of the word "consumed in the using."

The cost of equipment such as has been described, for professional use, cannot be deducted as expense in the year acquired. Examples of this class of property are automobiles, office furniture, medical, surgical and laboratory equipment of more or less permanent nature, and instruments and appliances constituting a part of the physician's professional outfit, to be used over a considerable period of time, generally over one year. Books of more or less permanent nature are regarded as equipment and the purchase price is therefore not deductible.

Although the cost of such equipment is not deductible in the year acquired, nevertheless it may be recovered through depreciation deductions taken year by year over its useful life, as described later.

No hard and fast rule can be laid down as to what part of the cost of equipment is deductible each year as depreciation. The amount depends to some extent on the nature of the property and on the extent and character of its use. The length of its useful life should be the primary consideration. The most that can be done is to suggest certain average or normal rates of depreciation for each of several classes of articles and to leave to the taxpayer the modification of the suggested rates as the circumstances of his particular case may dictate. As fair, normal or average rates of depreciation, the following have been suggested: automobiles, 25 per cent a year; ordinary medical libraries, x-ray equipment, physical therapy equipment, electrical sterilizers, surgical instruments and diagnostic apparatus, 10 per cent a year; office furniture, 5 per cent a year.

The principle governing the determination of all rates of depreciation is that the total amount claimed by the taxpayer as depreciation during the life of the article, plus the salvage value of the article at the end of its useful life, shall not be greater than its purchase price. The physician must in good faith use his best judgment and claim only such allowance for depreciation as the facts justify. The estimate of useful life, on which the rate of depreciation is based, should be carefully considered in each individual case.

Medical Dues.—Dues paid to societies of a strictly professional character are deductible. Dues paid to social organizations, even though their membership is limited to physicians, are personal expenses and not deductible.

Postgraduate Study.—The Commissioner of Internal Revenue holds that the expense of postgraduate study is not deductible.

Traveling Expenses.—Traveling expenses, including amounts paid for transportation, meals and lodging, necessarily incurred in professional visits to patients and in attending medical meetings for a professional purpose, are deductible.

Automobiles.—Payment for an automobile is a payment for permanent equipment and is not deductible. The cost of operation and repair, and loss through depreciation, are deductible. The cost of operation and repair includes the cost of gasoline, oil, tires, insurance, repairs, garage rental (when the garage is not owned by the physician), chauffeur's wages, and the like.

Deductible loss through depreciation of an automobile is the actual diminution in value resulting from obsolescence and use and from accidental injury against which the physician is not insured. If depreciation is computed on the basis of the average loss during a series of years, the series must extend over the entire estimated life of the car, not merely over the period in which the car is possessed by the present taxpayer.

If an automobile is used for professional and also for personal purposes—as when used by the physician partly for recreation, or so used by his family—only so much of the expense as arises out of the use for professional purposes may be deducted. A physician doing an exclusive office practice and using his car merely to go to and from his office cannot deduct depreciation or operating expenses; he is regarded as using his car for his personal convenience and not as a means of gaining a livelihood. What has been said in respect to automobiles applies with equal force to horses and vehicles and the equipment incident to their use.

MISCELLANEOUS

Contributions to Charitable Organizations.—For detailed information with respect to the deductibility of charitable contributions generally, physicians should consult the official return blank or obtain information from the collectors of internal revenue or from other reliable sources. An individual taxpayer can deduct such contributions only to the extent that they do not exceed 15 per cent of his adjusted gross income. The physician may not deduct as a charitable contribution the value of services rendered an organization operated for charitable purposes.

Bad Debts.—Physicians who make their returns on a cash receipts and disbursements basis, as most physicians do, cannot claim deductions for bad debts.

Taxes.—Taxes generally, either federal or state, are deductible by the person on whom they are imposed by law. Both real and personal property taxes are deductible; but so-called taxes, more properly assessments, paid for local benefits, such as street, sidewalk and other like improvements, imposed because of and measured by some benefit inuring directly to the property against which the assessment is levied, do not constitute an allowable deduction from gross income. Physicians may deduct state gasoline taxes and state sales taxes. In some states sales taxes are imposed on the seller, but, if they are passed on to the buyer, the latter may deduct them.

State income and use taxes are deductible; federal income taxes are not. Federal import, excise or stamp taxes are deductible only to the extent that they are attributable to business activities. State automobile license fees are deductible. If a state or local fee is imposed for regulatory purposes, and not to raise revenue, the fee may not ordinarily be deducted as a tax. If such fees, however, are classifiable as a business expense, they are deductible as such. Annual registration fees imposed on physicians probably come within the category of regulatory fees and should be deducted as a business expense rather than as taxes. Local and state occupational taxes imposed on physicians are deductible either as taxes or as a business expense, depending on the purpose for which the tax is imposed.

The excise taxes imposed on employers by section 804, title VIII, and section 901, title IX, of the Social Security Act, commonly referred to as old age and unemployment benefit taxes, are deductible annually by employers in computing net income for federal income tax purposes. If the taxpayer's return is made on a cash basis, as are the returns of practically all physicians, the taxes are deductible for the year in which they are actually paid. If the return is made on an accrual basis, the taxes are deductible for the year in which they accrue, irrespective of when they are actually paid. Employees, including physicians whose employment brings them within that category, may not deduct the tax imposed on them by section 801, title VIII, of the Social Security Act, generally referred to as the old age benefits tax. If, however, the employer assumes payment of the employee's tax and does not withhold the amount of the tax from the employee's wages, the amount of the tax so assumed may be deducted by the employer, not as a tax paid but as an ordinary business expense.

Medical Expense.—A taxpayer may deduct amounts expended for medical, dental and hospital care for himself, his spouse or a dependent, not compensated for by insurance or otherwise, including amounts paid for accident and health insurance, according to a prescribed formula. Deductions will be permitted to the extent that such expenses exceed 5 per cent of the adjusted gross income of the taxpayer but not in excess of $2,500 in case of a taxpayer with more than one exemption, or $1,250 in case of a taxpayer with only one exemption.

Laboratory Expenses.—The deductibility of the expenses of establishing and maintaining laboratories is determined by the same principles that determine the deductibility of corresponding professional expenses. Laboratory rental and the expenses of laboratory equipment and supplies and of laboratory assistants are deductible when under corresponding circumstances they would be deductible if they related to a physician's office.

Losses by Fire or Other Causes.—Loss of and damage to a physician's equipment by fire, theft or other cause, not compensated by insurance or otherwise recoverable, may be computed as a business expense and is deductible, provided evidence of such loss or damage can be produced. Such loss or damage is deductible, however, only to the extent to which it has not been made good by repair and the cost of repair claimed as a deduction.

Insurance Premiums.—Premiums paid for insurance against professional losses are deductible. This includes insurance against damages for alleged malpractice, against liability for injuries by a physician's automobile while in use for professional purposes, and against loss from theft of professional equipment and damage to or loss of professional equipment by fire or otherwise. Under professional equipment is to be included any automobile belonging to the physician and used for strictly professional purposes.

Expense in Defending Malpractice Suits.—Expense incurred in the defense of a suit for malpractice is deductible as a business expense.

Sale of Spectacles.—Oculists who furnish spectacles, etc., may charge as income money received from such sales and deduct as an expense the cost of the article sold.

Washington Letter

(From a Special Correspondent)

Feb. 5, 1947.

Training of Six Hundred in Psychiatric Work Advocated by Mental Health Council

The National Advisory Mental Health Council, meeting here, has approved the training this year of six hundred psychiatric personnel, including one hundred and fifty psychiatrists and the same number in the related fields of psychology, psychiatric social work and nursing. The program was adopted to meet a national shortage of psychiatric personnel. Dr. Edward A. Strecker of Philadelphia, head of the council's training committee, said that the figure seemed inadequate in view of his estimate that "we have less than one third of the psychiatrists needed to meet the minimum psychiatric needs of the country."

Federal Officials Puzzled by Large United States Consumption of Sleeping Pills

Government officials are reported to be puzzled by the heavy consumption of sleep-producing barbiturate drugs each year. Experts say that the 1945 production of 582,000 pounds was enough to put every American man, woman and child to sleep each night for two weeks. The pharmaceutical and drug industry, represented by the National Drug Trade Council, is campaigning for stronger controls and has sponsored a model law before state legislatures. Representative Rogers of Massachusetts has introduced a bill in Congress to place barbiturate compounds under the Federal Narcotics Act.

Delays in Providing Hospitalization for Veterans

Representative Rogers of Massachusetts has announced that the House Veterans Committee, of which she is chairman, will investigate the adequacy of hospitals operated by the Veterans Administration. A subcommittee, headed by Representative Kearney, New York Republican, will check on complaints that former servicemen are required to wait too long for hospitalization. Mrs. Rogers declares that an acute shortage of hospital beds for women veterans exists, despite repeated requests for more. She stated: "We set aside 500 million dollars for veterans' medical research and care three years ago when we passed the GI bill of rights, and I'd like to see that program taking shape."

Convictions Against Eight Limb Manufacturers Reversed by Court

The United States Court of Appeals has reversed antitrust convictions which were handed down in district court last May against eight artificial limb manufacturers. The five corporations and three individuals involved in the reversal were among eighty indicted for conspiracy to fix the price of artificial limbs in violation of the Sherman Anti-Trust Act. The court based its reversal on "an abuse of discretion" by the trial judge. Sixty-three of the accused had entered pleas of nolo contendere (no contest). Those winning reversals were J. E. Hanger, Inc., of Washington, D. C.; separate corporations of the same name in Illinois, Indiana, Missouri and Texas; Joseph F. Branham, vice president of the Illinois firm; McCarthy Hanger, president of the Missouri corporation, and Hugh H. Hanger, who operates a separate business in Philadelphia.

Outlines Work of World Health Organization

The World Health Organization was created to elevate the physical and mental health of all people, Dr. Frank A. Calderone, director of the headquarters office of the interim group, told delegates to the twenty-first Women's Patriotic Conference on National Defense. He said sixty-one nations had given enthusiastic support to the organization.

National Birth Rate Shows Increase

The U. S. Public Health Service has estimated the number of births registered for the first eleven months of 1946 to be 2,922,000, 16 per cent above the 1945 figure. A small decrease in deaths was recorded in the same period, the estimate of 1,275,000 being 16,000, or 1.3 per cent, more than in 1945.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Industrial Health Hazards

A bill introduced by Representative Norton, New Jersey, H R 475, *would authorize an annual appropriation of $5,000,000 for the purpose* of enabling the United States, through the Department of Labor, to cooperate with state agencies administering labor laws in the establishment and maintenance of safe and proper working conditions in industry and in the preparation, promulgation and enforcement of regulations to control **industrial health hazards.**

A somewhat similar bill is pending in the Senate introduced by Senator Johnston, South Carolina, for himself and Senator Morse, Oregon, S. 101, the purpose of which is stated to be to "assist the several states in establishing and maintaining **safe working conditions** *in industry and in promoting the observance of safety precautions and* rules by employers and employees in industry"

Medical Administrator in Navy Hospital Corps

A bill has been introduced in the Senate by Senator Gurney, South Dakota, S 238, to establish the commissioned grade of **medical administrator** in the Hospital Corps of the Navy Officers of the grade of medical administrator, it is proposed, will have the rank of captain, commander, lieutenant commander, lieutenant, lieutenant (junior grade) or ensign The total number of medical administrators will not exceed 3 per cent of the authorized strength of the Hospital Corps

G. I. Bill of Rights

A number of bills are pending to amend the Servicemen's Readjustment Act of 1944 with respect to the **education and training of veterans.** One of these S 326, introduced by Senator Pepper, Florida, would, among other things, provide that a veteran while enrolled in and pursuing a course of education or training will be paid a subsistence allowance *of $100 a month* if without a dependent, $125 a month if he has one dependent, and $150 a month, if he has two or more dependents If such a veteran also receives compensation for productive labor, he will be entitled to receive such lesser sums, if any, as subsistence or dependency allowances, as may be determined by the administrator, provided that the rate of such allowance plus the compensation received shall in no event exceed $350 per month for a veteran without a dependent, *$375 per month* if he has one dependent or $400 per month if he has two or more dependents.

Miscellaneous

Senator Gurney, South Dakota, has introduced a bill to **reorganize** ***the Nurse Corps*** *of the Navy and of the Naval Reserve, S. 322.*

Another bill introduced by Senator Gurney, South Dakota, S. 334, proposes to establish a **Medical Associated Sciences Corps** in the Medical Department of the Navy.

The enactment of a **Federal Insecticide, Fungicide and Rodenticide Act** is proposed by H R 1237, introduced by Representative August H Andersen, Minnesota.

Congressman Rogers, Massachusetts, has introduced, by request, H. R. 186, a bill to provide follow-up outpatient **medical treatment for veterans** suffering from non-service connected disabilities for which they have been hospitalized pursuant to laws administered by the Veterans Administration

A bill introduced by Congressman Cole, New York, H R 1275, would authorize the Secretary of the Navy to promulgate regulations providing for the **reimbursement of persons in the naval service** for the cost of emergency or necessary medical services, including hospital service and medicines, from civilian sources when the person receiving the service was in a duty status Such reimbursement will be authorized *only if it is determined that medical service was not available from* a federal source

STATE LEGISLATION

California

Bills Introduced.—A 438, to amend the **chiropractic act,** proposes that no person shall be denied admission to any school of chiropractic or *to examination and licensure* as a chiropractor because of blindness A. 487, to amend the **business and professions code,** proposes that the acceptance by any person licensed under the business and professions code of any rebate, refund, commission or unearned discount, whether in the form of money or otherwise, as compensation for referring patients to any person, firm, corporation or association constitutes unprofessional conduct S. 134, to amend the **Business and Professions Code,** proposes to *authorize* the issuance of a naturopathic physician's certificate and defines naturopathy to include "physiotherapy, manual, mechanical, and manipulative therapy, psychoanalysis, psychotherapy, electricity, non-narcotic herbs, supplemental foods, vitamins, air, water, diet, massage, endocrinology, biochemistry, accident and occupational therapy and all other natural methods consistent with naturopathic science"

Indiana

Bills Introduced—H. 30 proposes to require all **physicians to report** the name, age and address of every person diagnosed as having epilepsy or similar disorder characterized by lapses of consciousness, to the state board of health S 41 proposes the creation of a **board of natural therapeutic physicians.** The practice of natural therapy is defined to mean "analysis and treatment of human ailments, as taught in *naturopathic schools* and colleges and is hereby further defined to mean the use and practice of psychological, mechanical and material health sciences to aid in purifying, cleaning and *normalizing* human tissues for preservation or restoration of health according to the fundamental principles of anatomy, physiology and applied psychology as may be required Naturopathic practice employs, among other agencies, heat, light, water, electricity, psychology, diet, massage and other manipulative methods These agencies are known as psychotherapy, suggestotherapy, hydrotherapy, electrotherapy, mechanotherapy, biochemistry, external applicances, mechanical and electrical appliances, hygiene, heliotherapy and dietetics" S 67 *proposes to authorize the state board* of health to purchase and distribute blood plasma throughout the state, *without charge*

New York

Bills Introduced.—S 227, to amend the law in relation to **prenatal examinations,** proposes that the test shall be for the Rh factor of a pregnant woman as well as for syphilis S 313 proposes the creation of a **board of examiners in massage** and defines massage as "the stroking, kneading, *tapping or rolling* with the hands, or with other instrumentalities, of the human body for hygienic or remedial purposes, for the purposes of relieving, alleviating, or reducing affected parts thereof, but shall not include reduction of a fracture or dislocation of a bone" S 109 proposes **to redefine a podiatrist** as one who "practices podiatry within the meaning of this article who holds himself out as being able to diagnose, treat, operate or prescribe for *any disease,* pain, *injury, deficiency, deformity* or physical condition of the human feet, and/or who shall either offer or undertake by any means or method to diagnose, treat, operate or prescribe for any disease, pain, injury, deficiency, deformity or physical condition of the same within the following limitations operations on the feet shall be limited to minor surgery; the use of anesthesia shall be limited to local *anesthetics* and postoperative sedatives, and podiatrists may not treat other than *local manifestations* in the feet of systemic diseases"

North Dakota

Bill Introduced.—H. 52, to amend the law relating to hospitals, proposes, among other things, rules and regulations for the licensing of maternity homes and maternity hospitals

Oklahoma

Bills Introduced.—H. 50 proposes to make it unlawful for any person engaged in what *is generally known* as the science *or system of the* healing art, or the practice of osteopathy, chiropractic, rubbing or manipulation of muscles, adjustment or any other method, either by hand or by mechanical device, to make or profess to be able to make any diagnosis, anatomical, pathological, differential or by exclusion, of any sickness, illness or disease or to prescribe, require or recommend the taking or use of any drug unless such person shall have the ***requisite qualifications*** *and be admitted to the practice of medicine* as a licensed physician and surgeon in the state of Oklahoma. H. 56 proposes to authorize the state board of medical examiners to *accept* **in lieu of the one year's internship** requirement proof that the applicant for a license was commissioned and served in the armed forces during World War II as a physician or surgeon.

Oregon

Bill Passed.—H 7 passed the house January 22 It proposes to require all physicians licensed by the state board of medical examiners to report immediately to the local *health officer the name, sex, date* of birth and address of every person diagnosed as having **epilepsy,** or similar disorder characterized by momentary or prolonged lapses of consciousness or control, which is or may become chronic

South Dakota

Bill Introduced.—*H. 18 proposes* rules and regulations for the licensing of **chiropractic hospitals,** sanatoriums or related institutions by the board of chiropractic examiners.

Texas

Bills Introduced.—S. 29 proposes an act to require the licensing, inspecting and **regulating of hospitals** and related institutions and to *create a hospital licensing council* S 35 proposes the creation of a **state board of examiners** in the basic sciences, of anatomy, physiology, chemistry, bacteriology, pathology and hygiene and public health and proposes to require that all persons desiring to practice a healing art must first obtain a certificate from such board of examiners. The term healing art is defined to include "any system, treatment, operation, diagnosis, prescription or practice for the ascertainment, cure, relief, *palliation, adjustment* or correction of any human disease, ailment deformity, injury or unhealthy or abnormal physical or mental condition" Exempted from *the proposal* would be licensed dentists optometrists, nurses, chiropodists, masseurs, commissioned or contract surgeons of the United States Army, Navy or Public Health and Marine Hospital Service, and physicians licensed in other states called in consultation in Texas S 59 proposes the creation of a **naturopathic examining board** and defines naturopathy to mean "the use and practice of Drugless Therapy by dietetics, dehydrated foods, phytotherapy, nutritional *mineral and vitamin therapy,* autotherapy, mechanotherapy and mechanical appliances, vibrotherapy, pneumatotherapy, electrotherapy, light therapy—visible and invisible, thermotherapy, cryotherapy, hydrotherapy, and Physical Therapy by articular manipulations, massage, gymnastics; and Psychological Therapy by psychotherapy, suggestotherapy, *zone therapy and neurotherapy, and Radiography.*"

Virginia

Bills Passed.—S. 27-X passed the senate January 16. It proposes the enactment of a **hospital licensing** and inspection law but would exempt therefrom hospitals operated for the practice of the religious tenets of any church in the ministration to the sick and suffering by mental or spiritual means without the use of any drug or material remedy provided the statutes or regulation on sanitation are complied with. S. 28-X passed the senate January 15. It proposes the establishment within the department of health of a division of hospital survey and construction to make a **survey of existing hospitals**, develop a state plan for the construction of nonprofit hospitals in the state etc. The proposal also provides for the appointment of a hospital advisory council and authorizes the commissioner of the state department of health to apply for federal funds to assist in carrying out the survey and planning activities contemplated by the proposal and to receive federal funds in behalf of applicants. S. 31-X passed the senate January 16. It proposes a licensing law for hospitals for the care or treatment of the insane, epileptic or feebleminded persons or persons addicted to the intemperate use of narcotic drugs, alcohol or other stimulants.

West Virginia

Bills Introduced.—H. 50 and S. 50 propose to make it mandatory for every physician practicing in the state **to report in writing to the board of control** the name, age, sex, race, home address and type of disease of every person having tuberculosis who comes under his observation or care H. 51 and S. 51 propose regulations for the **licensing of hospitals**, sanatoriums, rest homes and related institutions.

Wisconsin

Bill Introduced.—A. 52 proposes that any person who shall **torture any animal** of any kind whatsoever shall be deemed guilty of a misdemeanor and proposes further that animals may be used for scientific experimentation and research if not subjected to cruelty or torture. Cruelty and torture are not defined by the proposal.

Council on Medical Service

RURAL ENROLMENT EXPERIENCE

From a Report by

F. K. HELSBY
Director of Surgical Care, Inc.
Kansas City, Mo.

The Blue Cross Hospital Service and Surgical Care, Inc., of Kansas City, Mo. report a typical rural enrolment in their experience as that of Lafayette County, 40 miles from the metropolitan area of Kansas City.

Lafayette County has an approximate population of 28,000 people, and two towns in the county have 5,000 population each, namely Lexington and Higginsville. There are seven other towns in the county with less than 1,000 people in each, some just a store and grain elevator.

Previous to our recent enrolment campaign we had an active medical plan with the Farm Bureau and two firms, a shirt factory and a shoe factory, perhaps ten small retail establishments with less than fifteen employees.

It was decided to conduct an enrolment on a countywide basis, open to every one.

The first step was to present the program to every civic club in the county. The plan representative attended every chamber of commerce, Lions Club, Rotary Club, American Legion or other similar meeting held in a period of two weeks prior to actual enrolment dates. Sponsorship and cooperation were obtained from all these civic bodies.

The next step was to arrange convenient places in each community where applications could be obtained, information supplied and literature distributed. This necessitated a training program with an employee of the bank, doctor's office, grain elevator or the particular business institution designated as an enrolment place.

The third and final step was an advertising campaign designed to bring the people into these places to sign up. This was accomplished mainly by the use of the county weekly newspapers, in the form of both paid-for display advertising and, very important, free news stories on the front pages.

In the final stages a sound truck was used on Saturday nights in the towns. This equipment was donated by the merchants of Higginsville.

Fifteen hundred members were obtained in eight days.

THE MIDDLE ATLANTIC STATES

Regional Conference of the American Medical Association Council on Medical Service

Two years ago the Council on Medical Service began its program of sponsoring conferences in various areas throughout the country. These meetings are generally termed Conferences on Medical Service. Discussion centers on problems in which the five or six states in the area represented are particularly interested. Key speakers are brought to the meeting to lead the discussion.

Last year, in the area including Virginia, Maryland, Delaware, New Jersey, New York and Pennsylvania, the conference members decided on a permanent organization. The Conference selected F. F. Borzell, M.D., Philadelphia, as chairman; Thomas A. McGoldrick, M.D., Brooklyn, as vice chairman, and William Bates, M.D., Philadelphia, as secretary treasurer. This new group set up a schedule of semiannual meetings. Two meetings each year, spring and fall, are to be general conferences on problems of medical service. An executive committee consisting of a representative of each state develops the programs and administers the business of the conference. The various state medical societies have contributed funds for incidental expenses.

The third semiannual meeting of the conference was held in Philadelphia on Thursday, Nov. 21, 1946. The attendance totaled almost fifty, including guest representatives from Ohio and West Virginia.

The program centered around four major subjects with ample opportunity for discussion by those present. Subjects and speakers or moderators were as follows:

Round Table on Medical Problems Involved in the Bituminous Coal Agreement

Moderator: Walter B. Martin, M.D., Norfolk, Va.

Veterans Administration Medical Program

Col. James C. Harding, Veterans Administration

Reports of the States on Veterans Administration Program

Round Table on Proposed Changes in the Taft Bill

Moderators: Frederic J. Quigley, M.D., Union City, N. J., and Louis H. Bauer, M.D., Hempstead, N. Y.

Present Activities of the Council on Medical Service

Thomas A. Hendricks, American Medical Association

This conference and the two earlier conferences have definitely proved of value to those participating. Every effort has been made to keep them from degenerating into purely gab fests and to channel the talks, questions and answers into instructive pros and cons. In general they are designed to make possible a direct exchange of information and ideas between the state medical societies and the American Medical Association.

The "Regional Conferences" are a regular part of the Council's program. The Middle Atlantic States Regional Conference is the first to be organized into a formal, permanent group. Whether this will become the pattern for others remains to be determined. Perhaps other areas will wish to follow this lead.

Coming Medical Meetings

Annual Congress on Medical Education and Licensure, Chicago, Palmer House, Feb. 10-11. Dr. Victor Johnson, 535 N. Dearborn St., Chicago 10, Secretary.

American Association for the Study of Goiter, Atlanta, Ga., April 3-5. Dr. Thomas C. Davison, 478 Peachtree St., N. E., Atlanta 3, Secretary.

Central Surgical Association, Chicago, Feb. 20-22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd., Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Earlson, 1133 Medical Arts Bldg., Dallas, Secretary.

Mid-South Postgraduate Medical Assembly, Memphis, Tenn., Feb. 11-14. Dr. Arthur F. Cooper, 1479 Carr Ave., Memphis, Secretary.

Missouri State Medical Association, Kansas City, March 30-April 2. Mr. Thomas R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Executive Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24-27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Southwest Allergy Forum, Shreveport, La., March 31-April 1. Dr. Sim Hulsey, 505 Medical Arts Bldg., Fort Worth, Texas, Secretary.

GOVERNMENT SERVICES

ARMY

MODEL OF NEW ARTIFICIAL HAND

Major Gen. Norman T. Kirk, the Surgeon General, announced January 22 a new artificial hand which represents a major advance in the manufacture of prostheses for amputees. This hand is said to be far superior mechanically and cosmetically to anything that has been perfected to date. It has the appearance of a natural hand, whereas heretofore the best that could be provided from a utility standpoint was the hook hand. The new devices will not be on the market until civilian industry gets them into production. This advance has been completed by the Army's Prosthetics Research Laboratory, Army Medical Center, Washington, D. C., although a research program had been started previously in army hospitals throughout the country.

AURAL REHABILITATION CENTER OPENED

The only army center for the rehabilitation of the hard of hearing was formally opened January 19 at the Forest Glen Section of Walter Reed General Hospital, Washington, D. C., where a specially selected and highly trained staff of about 50 has been assembled. Among others the staff comprises 12 instructors in speech reading, 6 technician experts in testing and fitting hearing aids, 6 technicians to teach how to use the device most efficiently, 5 speech correctionists and smaller numbers of specialists in other fields. The center has sufficient staff, space and equipment to care for 250. The "students" will be those who have finished with treatment and surgery and now require rehabilitation. A building has been refitted and remodeled into soundproof rooms, lecture halls, laboratory and offices where the hearing handicapped can have their disability appraised and corrected. It is planned that the eight weeks rehabilitation course will transform every student into an independent adjusted individual capable of resuming his or her place in society with the least possible handicap economically or socially. In the opening ceremony Major Gen. Norman T. Kirk, the Surgeon General, summarized the advances in ng and technic evolved for this type of treatment in the s army centers during the war, which centers have now consolidated into the section at Forest Glen, which e under the direction of Col. Guy A. Owsley, M. C., . S. Army.

THE AIR SURGEON RECEIVES AWARD

The Institute of Aeronautical Sciences, New York, on January 27 presented the John Jeffries Award to Brig. Gen. Malcolm C. Grow, U. S. Army, the Air Surgeon. General Grow graduated from Jefferson Medical College and joined the medical reserve corps as captain in 1917 and was commissioned in the regular corps in 1920. He served in Siberia during the first world war and in the European theater in the second world war, more recently in Guam, and was appointed the Air Surgeon in January 1946 to succeed Major Gen. David N. W. Grant, who retired. For years he carried on experimental work in the development of winter flying clothing. This award is presented annually for outstanding contribution to the advancement of aeronautics through medical research. The recipient is selected by a committee.

DIETITIANS NEEDED NOW BY ARMY

The War Department has announced the immediate need for fifty additional Medical Department dietitians for assignment to army hospitals in the United States and overseas. Initial appointments are made in the grade of second lieutenant, and the salary is $2,160 a year. In addition, 70 cents a day subsistence allowance and quarters are provided. There is a 5 per cent increase in base pay for every three years of service. A 10 per cent increase in base pay is authorized for foreign service. Applicants must be unmarried. An applicant who meets the educational, citizenship and age requirements will be authorized to report (travel at her own expense) at an army post for physical examination.

She must have a degree from an approved college with a major in either foods and nutrition or institution management and must have completed a dietitians' training course approved by the Surgeon General. Two years' experience in a hospital approved by the Surgeon General may be substituted for the training course, provided the experience includes diet therapy, planning menus, supervising employees in food preparation and service, food cost control, and ordering food supplies and equipment. One year of this experience must have been within the last ten years.

Medical Department dietitians are women members of the Medical Department, with commissioned officer status in the Army of the United States. Four hundred Medical Department dietitians are now on duty. Application should be made to the Surgeon General, attention Dietetic Consultants Division, Pentagon Building, Washington 25, D. C.

PSYCHIATRISTS CONFER AT WAR DEPARTMENT

Psychiatrists who are consultants to the Secretary of War met in Washington, January 20-21, to discuss future War Department neuropsychiatric policies, Major Gen. Norman T. Kirk, the Surgeon General, announced. All doctors attending the conference were assigned to active duty in the Army Medical Department during the war.

Dr. William C. Menninger, Topeka, Kan., presided at the meeting; others participating and their panel assignments were:

ORGANIZATION

Dr. Malcolm J. Farrell, chairman, Waverly, Mass.
Dr. Alan Challman, Minneapolis.
Dr. Edward G. Billings, Denver.
Dr. Perry C. Talkington, Dallas, Texas.
Dr. Lloyd J. Thompson, Winston-Salem, N. C.
Dr. William J. Bleckwenn, Madison, Wis.

PREVENTION

Dr. Manfred S. Guttmacher, chairman, Baltimore.
Dr. Franklin G. Ebaugh, Denver.
Dr. Alfred O. Ludwig, Boston.
Dr. Oscar B. Markey, Cleveland.
Dr. Paul L. Schroeder, Chicago.
Dr. Joseph S. Skobba, Atlanta, Ga.
Dr. John W. Appel, Philadelphia.

PERSONNEL POLICY

Dr. Frederick Hanson, chairman, Montreal.
Dr. Clarke H. Barnacle, Denver.
Mr. William H. Dunn, New York.
Dr. John M. Flumerfelt, Cleveland.
Dr. Lauren H. Smith, Philadelphia.
Dr. Ivan C. Berlien, Detroit.

SELECTION AND DISCHARGE

Dr. Wilford Bloomberg, chairman, Framingham, Mass.
Dr. Norman Q. Brill, Washington, D. C.
Dr. Roscoe W. Cavell, Detroit.
Dr. M. Ralph Kaufman, New York.
Dr. John M. Murray, Boston.
Dr. Donald F. Hastings, Minneapolis.

POTENTIAL EMERGENCIES

Dr. Calvin S. Drayer, chairman, Philadelphia.
Dr. Henry W. Brosin, Chicago.
Dr. William H. Everts, New York.
Dr. John H. Greist, Indianapolis.
Dr. Douglas A. Thom, Boston.

BRIGADIER GENERAL HILLMAN RETIRES

Brig. Gen. Charles C. Hillman, M. C., U. S. Army, has retired from active service as of January 31 and has been appointed director of the Jackson Memorial Hospital, Miami, Fla. Dr. Hillman is a graduate of Rush Medical College, 1911, and entered the service May 12, 1913. During the recent war he was director of professional services in the Surgeon General's Office and later commanding officer of Letterman General Hospital, San Francisco, for which service he was awarded the Legion of Merit with Oak Leaf Cluster.

ARMY AWARDS AND COMMENDATIONS

Colonel Thomas L. Ferenbaugh

The Legion of Merit was recently awarded to Col. Thomas L. Ferenbaugh, Columbus, Ohio. The citation read as follows: "Col. Thomas L. Ferenbaugh performed meritorious service from September 1942 to February 1945. As Medical Director, Camp Gordon, Johnston, Fla., he rapidly organized an efficient medical service during an emergency. As Post Surgeon and Commanding Officer, Station Hospital, Camp Forrest, Tennessee, he ably maintained this unit as a base hospital for the entire Tennessee Maneuver Area. Later he reorganized this Station Hospital into a Prisoner of War General Hospital, which functioned smoothly and efficiently, maintaining high professional standards. Colonel Ferenbaugh's leadership and untiring efforts established him as an exceptionally outstanding medical officer." Dr. Ferenbaugh graduated from Johns Hopkins University School of Medicine in 1909 and entered the service Sept. 20, 1909.

Major Benedict Nagler

The Army Commendation Ribbon has been awarded to Major Benedict Nagler, M. C., now with the Veterans Administration. The citation signed by Surg. Gen. Norman T. Kirk read, in part, "Your service with the Medical Department has been exceptional when compared with others of the same grade of similar positions, and I wish to commend you for your outstanding contribution as assistant chief and later as chief of the neuropsychiatric section, Cushing General Hospital, Framingham, Mass., from Oct. 27, 1943 to March 27, 1946." Dr. Nagler graduated from Hamburg University Medical School (Germany) in 1925 and entered the service from Newark, N. J.

Major John A. Layne

The Legion of Merit was recently awarded to Major John A. Layne, M. C., A. U. S., of Great Falls, Mont. The citation read as follows: "For meritorious services as Chief, Officers' Medical Section, Gardiner General Hospital from September 1944 to April 1946. Major Layne's efforts in organizing and conducting this important section of the hospital as demonstrated by his outstanding professional and administrative skill contributed greatly to the efficient operation of the installation. The services rendered by Major Layne won for him the respect and admiration of all patients and members of the staff with whom he came in contact." Dr. Layne graduated from the University of Minnesota Medical School, Minneapolis, in 1935 and entered the service Nov. 27, 1943.

Captain Alfred D. Heinemann

The Army Commendation Ribbon was recently awarded to Capt. Alfred D. Heinemann, M. C., A. U. S., of Dunkirk, N. Y.; "for outstanding and meritorious service in connection with military operations as medical officer, United States Forces, European Theater, Mission to the Netherlands," from Sept. 11, 1945 to July 1, 1946. After establishing his new office, said the citation, "without regard to his own health and welfare, he sacrificed every moment of his time to his patients. The care and precision with which he administered his broad knowledge of medical science averted serious consequences again and again. His devotion to duty; his sacrifices even above and beyond the call of duty, reflected great credit on himself and the military service." Dr. Heinemann, who graduated from the Universität Heidelberg Medizinische Fakultät, entered the service on May 6, 1944.

PUBLIC HEALTH SERVICE

ESTABLISH FEDERAL EMPLOYEES HEALTH DIVISION

For many years the U. S. Public Health Service has made studies of industrial and occupational hazards and has furnished professional advice on request to private industry and to agencies of the federal government. Now a federal employee health division has been created within the bureau of medical service of the Public Health Service which will develop standards and policies for federal employees health programs, provide private consultation services to the heads of departments and agencies of the federal government, including government owned and controlled corporations, review and appraise, on request, federal employee health programs already under way, and contract with departments and agencies of the federal government for the operation of such programs. Dr. John W. Cronin, a graduate of the University of Cincinnati College of Medicine and for many years an officer in the U. S. Public Health Service, will head the new Federal Employees Health Division.

EXAMINATION FOR APPOINTMENT OF PHARMACISTS

A competitive examination for appointment in the regular corps of the U. S. Public Health Service in grades of Junior Assistant, Assistant and Senior Assistant Pharmacists will be held during the period March 17 to April 16. Applicants, in addition to other things, must be citizens of the United States, have a diploma from a recognized pharmacy school, pass a physical examination performed by medical officers of the Public Health Service and have had a specified number of years of postgraduate professional training or experience. The entrance pay for these positions varies from $3,391 to $4,351 a year, depending on the appointment made and whether or not the person has dependents. Additional information may be obtained by writing the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

PERSONAL

Dr. Howard C. Rufus, Lancaster, Pa., a reserve officer in the U. S. Public Health Service, has been called to active duty and assigned to the Office of Indian Affairs, Juneau, Alaska.

MEETING OF ADVISORY MENTAL HEALTH COUNCIL

The second meeting of the National Advisory Mental Health Council was held in Washington, D. C., January 22-24 to lay further plans for a comprehensive national mental health program which although authorized by the national mental health act, approved by Congress last summer, cannot be inaugurated until funds are appropriated. However, a considerable number of applications for grants for research and training have already been received, according to Dr. Robert Felix, chief, Mental Hygiene Division, U. S. Public Health Service. The council studied these applications as a basis for future action when funds are available.

The members of the National Advisory Mental Health Council are:

Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine.
Dr. William C. Menninger, medical director, Menninger Clinic, Topeka, Kan.
Dr. John Romano, professor of psychiatry, University of Rochester Medical School, Rochester, N. Y.
Dr. Frank F. Tallman, commissioner of mental hygiene, Columbus, Ohio.
Dr. George S. Stevenson, medical director, National Committee for Mental Hygiene, New York.
Dr. David M. Levy, assistant professor, Department of Psychiatry, Columbia University College of Physicians and Surgeons, New York.

The members of the mental health study section, which acts in an advisory capacity to the council (The Journal, January 18, p. 187), are:

John Romano (chairman), Rochester, N. Y.
Nolan D. C. Lewis (vice chairman), New York.
Lawrence C. Kolb (executive secretary), U. S. Public Health Service.
Philip Bard, Baltimore.
Barney Brooks, Nashville, Tenn.
R. H. Felix, U. S. Public Health Service.
Eugene B. Ferris, Cincinnati.
Frank Fremont-Smith, New York.
Thomas M. French, Chicago.
Charles A. Janeway, Boston.
Kurt Lewin, Cambridge, Mass.
William Malamud, Worcester, Mass.
Margaret Mead, New York.
H. Houston Merritt, New York.
Arthur Mirsky, Cincinnati.
Lucille Petry, U. S. Public Health Service.
Marian C. Putnum, Boston.
David Rapaport, Topeka, Kan.
Fritz Redl, Detroit.
George Richard Wendt, Rochester, N. Y.
Abner Wolf, New York.
Harold G. Wolff, New York.
S. B. Wortis, New York.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

State Health Director Resigns.—Dr. Burton F. Austin, after twenty-six years of public health work in Alabama and serving as head of the state health department since 1942, has resigned to take up new duties as southeastern regional medical director for the American Red Cross with headquarters in Atlanta, Ga. Dr. Austin is a graduate of the University of Atlanta School of Medicine, University, 1917. He will be succeeded by Dr. Daniel G. Gill, Montgomery County health officer.

Grants to University.—The Medical College of Alabama at Birmingham has received a gift of $3,000 from Henry P. Johnston and the Birmingham *News-Age-Herald,* to be used for a study of deafness.——A gift of $2,500 from Judge Luther B. Liles, Anniston, to the Medical College of Alabama, Birmingham, for research work in blood diseases was announced last month by Dr. Roy R. Kracke, dean of the medical college. It is to be known as the Luther B. Liles Fund and will aid greatly in work now beginning in leukemia and other diseases of that nature, Dr. Kracke said.

CALIFORNIA

Stafford Warren Appointed Dean of Medical School.—Dr. Stafford L. Warren, professor of radiology at the University of Rochester School of Medicine and Dentistry, Rochester, N. Y., and during the war chief of the medical division for the entire atomic bomb project under the Manhattan District, has been appointed dean and professor of biophysics of the new medical school at the Los Angeles campus of the University of California. Dr. Warren received his medical degree from the University of California Medical School, San Francisco, in 1922 and thereafter served as assistant in pathology at Johns Hopkins University School of Medicine, Baltimore, as medical intern at the Massachusetts General Hospital and as resident physician in Collis P. Huntington Memorial Hospital, Boston. He has been a member of the University of Rochester School of Medicine and Dentistry faculty for twenty-one years. He will supervise plans for the medical buildings and university hospital of 500 beds to be built on the Los Angeles campus and assemble the faculty and staff for the new institution. He was a key figure at the first atomic bomb test in New Mexico and later was sent on missions to Nagasaki and Hiroshima to study the effects of the bombs dropped on Japan.

California Cancer Program.—Recently the cancer commission of the California Medical Association and the American Cancer Society, California division, jointly launched a program which included intensive public education in cancer and the establishment of more tumor centers. The cancer commission has formulated a plan to assist and encourage the organization of tumor consultation clinics in approved private hospitals throughout California. Tumor consultation centers, optional with the staffs of each hospital, will be subject to only the minimum standards for such clinics. Only a person referred by a private physician will be accepted, and the patient will be returned to him with recommendations. The American Cancer Society is financing a central office in each county as headquarters for a nurse, secretary and social service worker, who will be responsible for all records, program announcements and follow-ups on patients. A cancer information bureau will be established in the same office, which will give to patients the names of physicians who have indicated an interest in receiving referred cancer cases. Funds for needy patients allocated on a county basis will be available to approved private hospitals on application by the private physician from the campaign resources of the American Cancer Society. Several tumor consultation centers and detection centers are already in operation throughout California. It is hoped that many more can be organized soon to assist in the diagnosis and care of 39,000 patients now living with cancer in California.

COLORADO

State Health Director Appointed.—Dr. Roy L. Cleere, Denver, has been appointed by the state Civil Service Commission as state health director. Dr. Cleere, who is a graduate of the University of Texas, Medical Branch, Galveston, has been secretary of the Colorado State Board of Health and executive officer of the Colorado State Division of Public Health.

CONNECTICUT

Support Establishment of Health Districts.—The Connecticut State Medical Society has declared its intention of supporting a proposal of the state health department for the establishment of full time health districts throughout the state. Dr. Howard S. Colwell, New Haven, chairman of the society's public health committee, says that the endorsement of the health district system by the state medical society is an effort to assist in the development of modern public health services for the smaller towns and rural communities.

ILLINOIS

Violent Deaths in Cook County.—The annual report of the coroner of Cook County for 1946 shows a total of 674 deaths due to automobile accidents, 94 due to street car accidents, railroads 81, elevated railway 22, industrial accidents 115, motorcycle 8, bicycles 7, airplane 14. Falls accounted for 637 deaths, of which 148 were on the street, 273 on the floor and 44 from buildings. There were 310 homicides, of which 184 were due to shooting, and 431 suicides, the most common methods having been hanging in 165 cases and shooting in 110. The overall report has been said to show an increase in violent deaths of about 9.5 per cent. Cook County is occupied largely by the city of Chicago, which in 1940 had a population of 3,396,808.

Chicago

Society News.—The Chicago Medical Society, February 19, will be addressed by Dr. Arthur W. Allen of the Massachusetts General Hospital and Harvard Medical School, Boston, on "The Prevention and Treatment of Thrombosis in the Deep Veins of the Legs and Pulmonary Embolism," and by Dr. Waltman Walters, Mayo Clinic, Rochester, Minn., on "Vagotomy for Peptic Ulcer."

Food Poisoning Following Christmas Party.—Eighty employees of the Container Corporation of America are said to have been made ill as a result of eating turkey dressing served at a Christmas party. None of the victims were hospitalized. The president of the Board of Health of Chicago, Dr. Herman N. Bundesen, is reported to have said that the roast turkey and dressing had been prepared in advance and left standing twenty-four hours without refrigeration.

Hematology Research Foundation.—This organization, comprising a group of 1,250 civic minded young women, raises funds for research on blood diseases and related problems. All funds are allocated by the foundation's medical advisory council, whose members are Drs. Anton J. Carlson, Ludvig Hektoen, Andrew C. Ivy, Italo F. Volini, Raphael Isaacs, Louis R. Limarzi and Otto Saphir. The foundation has announced that the Ruth Reeder Fellowship has been awarded to Dr. Samuel S. Leiter, a graduate of the University of Pennsylvania School of Medicine and recently released from the navy after three and one-half years in submarine service. The Annette and Philip M. Marcus Fellowship has been awarded to Dr. B. Elizabeth Armstrong, a graduate of the University of Illinois Medical School now serving with the hematology laboratories of the Michael Reese and Cook County hospitals.

INDIANA

Annual Registration of Practitioners.—The house of delegates of the Indiana State Medical Association has gone on record as favoring through legislative action an annual registration of all practitioners of the healing arts. With a registration fee of two dollars it would be possible for the medical board to employ a full time investigator to obtain the necessary evidence for prosecution of violations of the law.

State Medical Officers.—Dr. Floyd T. Romberger, Lafayette, assumed the duties of president of the Indiana State Medical Association last month, succeeding Dr. Jesse E. Ferrell, Fortville. Dr. Cleon A. Nafe, Indianapolis, is president-elect, and Dr. Arthur F. Weyerbacher, Indianapolis, is association treasurer. Dr. Romberger, an anesthetist, was a member of the house of delegates of the state association and for fifteen years served as councilor, five of them as chairman.

Supreme Court Upholds Revocation of License.—The Indiana Supreme Court, Indianapolis, on January 4 is said to have upheld a ruling of the State Board of Medical Registration revoking the license of Dr. Addison G. Moore of Vincennes. The Supreme Court reversed a ruling of the Knox Circuit Court, which had previously overruled the action of the state board. Dr. Moore was convicted in November 1944 (THE JOURNAL, Sept. 8, 1945, p. 143) for violation of the federal narcotic laws.

MASSACHUSETTS

Seymour Gray Joins Harvard Staff.—Dr. Seymour J. Gray, formerly assistant professor of medicine at the University of Chicago, has been appointed assistant professor of medicine at Harvard Medical School and senior associate of medicine at the Peter Bent Brigham Hospital in Boston. Dr. Gray will divide his time between his duties as director of the gastrointestinal clinic at the hospital and as a member of the medical school group concerned with research in the biophysical laboratory. He recently returned from service at the Naval Medical Center, Bethesda, Md., as a lieutenant commander in the Naval Reserve.

Boston City Hospital Lectures.—Members of the medical profession are invited to attend the Tuesday evening lectures of the House Officers' Association of the Boston City Hospital held in Cheever Amphitheater of the Dowling Building at 7 p. m. Programs for February are as follows:

February 18. Dr. Alvan L. Barach, associate professor of clinical medicine, Columbia University College of Physicians and Surgeons, New York City, "Physiologic Therapy in Pulmonary Disease." Discussion: Dr. Maurice S. Segal, assistant professor of medicine, Tufts Medical School, Staff of Boston City Hospital.

February 25. Dr. Cornelius P. Rhoads, director, Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York City, "The Metabolic Aspects of Cancer."

MICHIGAN

Michigan Allergy Society.—"Pediatric Allergy" was the subject of an address by Dr. Bret Ratner, clinical professor of pediatrics, New York University College of Medicine, New York, when he addressed a joint meeting of the Detroit Pediatric Society, Detroit Dermatological Society and Detroit Otolaryngological Society January 17.

Mott Foundation Grant for Graduate Study.—The Mott Foundation has made a grant of $2,400 for the graduate study program of pediatrics and communicable diseases at the University of Michigan, Ann Arbor, to be used by a physician who will go to the Flint School Health Program after two years' study. The Mott Foundation, which was established several years ago by Mr. Charles S. Mott, Flint, vice president, General Motors Corporation, sponsors various educational projects and outdoor activities.

State Officers Night Meeting.—Genessee County Medical Society held a State Officers Night meeting in Flint January 14, Dr. Rolland C. Pochert, Owosso, councilor for the Sixth District, presiding. Dr. William Hyland, Grand Rapids, president of the Michigan State Medical Society, opened the program with a discussion of present problems of the medical profession. State Secretary Dr. L. Fernald Foster, Lansing, told of the Hill-Burton Hospital Construction bill, and William Burns, state executive secretary, discussed three impending bills in Congress as well as anticipated bills in the Michigan legislature. Various phases of the public relations program were explained by Hugh Brenneman, public relations council for the state society. Dr. Carleton Dean, East Lansing, of the Crippled Children's Commission spoke briefly on the status of the rheumatic fever program.

First Michigan Postgraduate Clinical Conference.—The first annual Michigan Postgraduate Clinical Conference is scheduled for the Book-Cadillac Hotel, Detroit, March 12-14. It has been instituted by the Michigan State Medical Society with the cooperation of the medical schools of the University of Michigan and of Wayne University and with the endorsement of the Wayne County Medical Society and the Michigan Foundation for Medical and Health Education. Registration and exhibits will open at 8:30 a. m. and conference programs begin at 9 o'clock each day. The opening speaker for Wednesday's session is Dr. Max R. Burnell, Flint, whose subject is "Gynecological and Obstetrical Problems in Industrial Medicine and Surgery." Throughout the day a variety of subjects will be discussed, each speaker being given twenty minutes. Exhibits will be in the Italian Garden, fourth floor. Clinical pathologic conferences—Wednesday a medical case, Thursday a surgical case—will be conducted from 4:20 to 5 p. m. The Wednesday evening session from 8 to 10 will be a symposium on "Protection against Infectious Disease," with Drs. Grover C. Penberthy, Hardy A. Kemp and Joseph A. Johnston, Detroit, and Thomas Francis, Ann Arbor, participating. Wednesday's evening session will be a panel discussion on "Preoperative and Postoperative Care of the Surgical Patient." Dr. Frederick A. Coller, Ann Arbor, will act as moderator on the panel made up of Drs. Luther C. Carpenter, Grand Rapids; Russell L. Mustard, Battle Creek, and Daniel J. Leithauser, Detroit. There is no Friday evening session. Half hour luncheon sessions are scheduled to begin at 1:15 following a lunch period. Members of the Michigan State Medical Society and all neighboring states and provinces are invited to attend this conference. Further information may be obtained by writing Dr. Grover C. Penberthy, chairman, 2020 Olds Tower, Lansing 8.

Personal. — Dr. William C. Ellet, Benton Harbor, was recently appointed to the state board of registration in medicine, replacing Dr. Francis J. O'Donnell, Alpena, resigned. Dr. Ellet was a board member before he went on active duty with the navy in 1941.——Dr. Frederick C. Kidner, for many years professor of clinical orthopedic surgery, Wayne University College of Medicine, Detroit, was appointed emeritus professor in the same department, December 26. The Detroit Board of Education cited Dr. Kidner for his "outstanding service and professional contributions to the college."——Dr. Oscar W. McKenna, Flint, has been elected to emeritus membership in the Michigan State Medical Society.

MISSOURI

Research on Edema.—An award of $17,110 by the Medical Sciences Branch of the Office of Naval Research was given to Washington University, St. Louis, recently for research on edema. The research work will be under the direction of Dr. Palmer H. Futcher, assistant professor of medicine.

Regional Scholarships.—Washington University School of Medicine, St. Louis, has established a program of regional scholarships to include at least seven annual awards to incoming freshmen and transferring students. The scholarships, under the Jackson Johnson Scholarship Fund, will be awarded to candidates of exceptional ability who have resided for at least three years in one of seven regions in the United States and who have completed their premedical training or their first two years of medical training in that region. At least one scholarship will be awarded in each region. Stipends will vary according to the financial need of the student, the maximum being $1,200 a year. Awards are renewable for the succeeding years of the medical course at the medical school if the student's record justifies renewal. Three graduate fellowships will also be awarded each year for five years under the Jackson Johnson fund. Applicants must be graduates of a recognized school of medicine and acceptable for admission to the School of Graduate Studies of Washington University as candidates for a doctorate degree. All applications must be completed by March 1 for the period beginning the following September.

NEW YORK

Bert Rickards Retires.—After many years' service in the state department of health, Mr. Bert R. Rickards, director, division of public health education since 1922, retired December 31. Through his initiative the department of health in New York was one of the first to inaugurate a program of home and farm safety, according to *Health News*.

Pratt Gift to Hospital Building Fund.—Mrs. Harold I. Pratt has given $144,900 to the building fund of the North Country Community Hospital, Glen Cove, Long Island, as a memorial to her late husband, first president of the hospital. The gift will be used to build a 23 room section in a proposed new building for the hospital. The $1,750,000 building fund will be launched next spring.

Tompkins County Postgraduate Lecture.—Included in postgraduate instruction arranged by its Council Committee on Public Health and Education, the Medical Society of the State of New York has arranged a lecture for the Tompkins County Medical Society, Monday, February 17, 8:30 p. m., at Tompkins County Memorial Hospital, Ithaca. Dr. Nelson G. Russell, professor of medicine emeritus, University of Buffalo School of Medicine, will speak on "Rheumatic Fever—Rheumatic Heart Disease."

Society News.—The Medical Society of the County of Albany held a scientific session January 22 at which Dr. Konrad Birkhaug, associate medical bacteriologist, New York State Division of Laboratories, discussed "Twenty Years of Experimental and Clinical BCG Vaccination in Scandinavia."——The Maternity Center Association invited Dr. Grantley Dick Read of London, England, to address it at the New York Academy of Medicine January 17 and to present his concepts of natural childbirth without pain.

Social Workers Institute.—The psychiatric social workers institute at Buffalo State Hospital January 25 was sponsored by the department of mental hygiene to provide training to improve the social service to patients in state institutions and give the social workers greater skill in handling their responsibilities in the community. Technics of the first interview with a mental patient were discussed. Other institutes have been scheduled, including one at the Psychiatric Institute, New York City, February 14, and another at Syracuse Psychiatric Hospital, February 21.

Health in an Aging Population.—A Conference on Health in an Aging Population will be held at the Rochester Academy of Medicine, March 13. It is sponsored by the Council of Social Agencies and with the participation of the School of Medicine and Dentistry of the University of Rochester, Medical Society of the County of Monroe, Rochester Academy of Medicine, Tuberculosis and Health Association of Rochester and Monroe County, Board of Education of Rochester and other agencies. There will be morning and afternoon sessions and a public evening meeting, with Louis Dublin of the Metropolitan Life Insurance Company as speaker.

Clinical Session on Pulmonary Tuberculosis.—A clinical session on chronic pulmonary diseases will be held Wednesday evening, February 19, at Cornell University Medical College amphitheater, New York City, at 8:15. "The Minimal Lesion in Pulmonary Tuberculosis" is the subject for Drs. Isidore D. Bobrowitz, Municipal Sanatorium, Otisville; Herman E. Hilleboe, U. S. Public Health Service, Washington, D. C., and William H. Roper, Fitzsimons General Hospital, Denver. Drs. J. Burns Amberson, Bellevue Hospital, New York City, and Haynes H. Fellows, Metropolitan Life Insurance Company, New York City, are scheduled for discussion to follow.

Western New York Counties Unite.—The closely integrated operation of the eight county medical societies in the Eighth Judicial District of New York was assured December 12 by the formation of the Advisory Council of Presidents and Secretaries of the Medical Societies of the Eighth Judicial District. Advocated by Dr. Porter A. Steele, president of the Medical Society of the County of Erie, the council was established to safeguard medicine's interests, the advancement of the profession and promotion of public welfare and health. The new relationship of these county societies will make possible the constant interchange of information and knowledge of equal interest to each county. Other judicial district branches in the state are expected to follow the Eighth District's example.

New York City

Health Education Conference.—The seventh annual health education conference of the New York Academy of Medicine January 21 took up the problems in health education, its myths and resistances and positive motivations. The afternoon session was a panel meeting with full audience participation to review and discuss materials presented during the morning session.

The Rothschild Lecture.—The ninth Marcus A. Rothschild Lecture will be delivered February 13 by Dr. Bernard Zondek, professor of gynecology and obstetrics, Rothschild Hadassah University Hospital, and director of hormone research, Hebrew University, Jerusalem, Palestine, on the "Mechanism of Action and Inactivation of the Estrogenic Hormone" in the auditorium of Beth Israel Hospital.

Laboratory Speeds up Blood Testing.—At a dinner meeting of the Society of Bacteriologists Dr. Israel Weinstein, health commissioner, reported that reorganization of the serological laboratory had made it possible to complete more than 5,000 blood tests a day as compared to 2,160, the previous high. This speed up of blood tests is expected to aid the fight against venereal disease. About 750,000 blood specimens were tested last year, he said.

Another Geriatric Research Laboratory.—It was recently stated that the city's first research laboratory devoted wholly to the study of geriatrics opened January 1 at the Brooklyn Hebrew Home and Hospital for Aged. The Home and Hospital of the Daughters of Jacob in this city now points out that it established such a research laboratory many years ago, the efforts of which have been directed exclusively to the field of geriatrics; also that the research has been so intensive that it has been necessary on two occasions to enlarge the facilities.

Construction Begins on Cancer Hospital.—Ground breaking ceremonies for the 300 bed James Ewing Memorial Hospital, 1st Avenue from 67th to 68th streets, Manhattan, a part of the Memorial Cancer Center, were held January 24. The city's new cancer hospital, which will cost $3,195,000 and will be completed in 1948, will be constructed of red brick to match the existing Memorial Hospital and the Sloan-Kettering Institute for Cancer Research now under construction. Dietary service has been decentralized so that each kitchen will serve two floors. Memorial Hospital made the land available for the city's new institution (The Journal, Dec. 21, 1946, p. 1020), and the medical and professional staff will be appointed on nomination by Memorial Hospital. The city will maintain and operate the hospital, and its purpose will be the care and treatment of long term cancer patients and research.

NORTH CAROLINA

Duke University News.—Dr. Eugene A. Stead, formerly of Atlanta, Ga., assumed his duties as professor of medicine at Duke University School of Medicine, filling the professorship held by Dr. Frederick M. Hanes, who died last March. Dr. Stead was formerly a professor at Emory University School of Medicine, Atlanta, and physician in chief, University division, Grady Hospital.——Dr. Raymond S. Crispell left Duke University November 4 to become director of the division of neuropsychiatry for Branch No. 5 of the Veterans Administration with headquarters in Atlanta. In addition he will be connected with the Emory University School of Medicine and the Georgia School of Technology, Atlanta.

OKLAHOMA

Personal.—Mr. Homer G. Goltry, superintendent of Enid General Hospital, Enid, has been chosen president of the Oklahoma Hospital Association.

Oklahoma Medical Research Foundation.—With interest in obtaining funds to carry on medical research in Oklahoma, the Oklahoma Medical Research Foundation has been chartered and is conducting a public education program throughout the major centers of the state. From offices at 208 Braniff Building, Oklahoma City, an organized fund raising movement with a $1,500,000 minimum goal will be initiated this spring, preceded by local meetings designed to focus the attention of the public on the need for and benefits from scientific research in medicine. Interest and enthusiasm of business and professional men outside the field of medicine have been noted.

PENNSYLVANIA

Society News.—Some recent developments regarding enucleation, modern implants and prosthesis with particular reference to the Cutler and Reudemann technics was the topic of discussion by Dr. Benjamin F. Souders, Reading, at the January meeting of the Reading Eye, Ear, Nose and Throat Society.

Philadelphia

Alfred La Boccetta Appointed Hospital Chief.—Dr. Alfred C. La Boccetta, recently appointed superintendent and medical director of the Philadelphia Hospital for Contagious Diseases, was honored at a testimonial dinner attended by more than a thousand guests January 20. The 34 year old physician is a graduate of Temple University Medical School, 1938, was a lecturer in pediatrics at the Temple University Medical School and has worked with Dr. Pascal L. Lucchesi, recently appointed head of the Philadelphia General Hospital, whom he succeeds.

Pittsburgh

Personal.—The Pittsburgh section of the American Chemical Society has chosen William Parks Yant, D.Sc., director of research, Mine Safety Appliances Company, for the 1946 Pittsburgh Award, which is bestowed annually for outstanding service to chemistry. Dean Herbert E. Longenecker, Ph.D., of the Graduate School, University of Pittsburgh, said that every activity of Mr. Yant has directly benefited humanity by improving health, reducing suffering and raising the general economic level. Many years ago Mr. Yant was chief chemist of the health division of the U. S. Bureau of Mines.

SOUTH CAROLINA

South Carolina Obstetrical and Gynecological Society.—During the 1946 postgraduate seminar of the Medical College of South Carolina early in December the South Carolina Obstetrical and Gynecological Society was organized with Drs. Lester A. Wilson, Charleston, president, Manly E. Hutchinson, Columbia, vice president, and Joseph Dechard Guess, Greenville, secretary-treasurer.

TENNESSEE

Flexner Lectures.—Sir Edward Mellanby, London, England, will be in residence as Flexner Lecturer for 1947 at Vanderbilt University School of Medicine, Nashville, during the two months' period of March and April. The five formal lectures of the series will be on the general subject "The Experimental Method in Problems of Nutrition."

Law Authorizing Practice of Naturopathy Repealed.—On January 16 the state legislature in both the house of representatives and the senate passed on third and final reading an act repealing the law approved in 1943 and amended in 1945 authorizing the practice of "Naturopathy" and creating an examining board. On January 17 Governor Jim McCord signed the act, and S. B. 15 became law. During the short period of time that this statute was on the books the Naturopathic Examining Board issued licenses to more than 900 "Naturopaths." All except about 185 of these "Naturopaths" live outside the jurisdiction of Tennessee and are practicing in other states. The 1947 act cancels all licenses issued in Tennessee.

TEXAS

University News.—A grant of $5,000 has been awarded to Southwestern Medical Foundation by the First Texas Chemical Manufacturing Company, Dallas, to carry on research in the department of pharmacology. The foundation also received from the Texas Division of the American Cancer Society three grants amounting to $17,500 for the study and treatment of cancer with radioactive substances. Grants totaling $11,915 have also been received for research work in the department of bacteriology and immunology at Southwestern Medical College, Dallas. The National Foundation for Infantile Paralysis gave $9,575, to be used in investigations on the influence of anesthesia on the course and outcome of experimental neurotropic virus infections, to be carried out by Dr. S. Edward Sulkin, chairman of the department. A grant of $2,340 from the U. S. Public Health Service has been made for research work concerning clinical and therapeutic action of penicillin and streptomycin.

VIRGINIA

Memorial Hospital Graduate Course.—The twentieth Annual Spring Graduate Course in Ophthalmology, Otology, Rhinology, Laryngology, Faciomaxillary Surgery, Bronchoscopy and Esophagoscopy has been announced for April 7-12 at the Patrick Henry Hotel, Roanoke, under the auspices of the Gill Memorial Eye, Ear and Throat Hospital. The lectures and demonstrations will be presented by men of high academic standing along with practical background and clinical practice.

WEST VIRGINIA

Cancer Essay Contest.—The West Virginia Cancer Society, Inc., is sponsoring an essay contest, open to students enrolled at West Virginia University or at any college in West Virginia. The subject is "The Cancer Problem," and discussion is limited to the best way to educate the people of West Virginia in matters pertaining to cancer control. The contest closes March 31, and entries are to be sent to the West Virginia Cancer Society, Inc., 1101 West Virginia Building, Huntington 1, W. Va.

Committees on Mental Hygiene and Diabetes.—Two special committees, authorized by the Council of the West Virginia State Medical Association, have been appointed by Dr. Wade H. St. Clair, president of the association, one on mental hygiene and the other on the study of diabetes in West Virginia. The committee on mental hygiene will contact the state health department and the mental institutions in the state and will study proposals for improvements, including increase in appropriations and appointment of additional trained personnel. It will keep in close contact with the National Committee for Mental Hygiene and affiliated organizations and will consider the creation of local mental hygiene groups. The council took action following the adoption of a resolution by the American Medical Association at the meeting at San Francisco last July. This resolution contemplates the development, with the help of each state medical association, "of an adequate statewide mental hygiene and mental diseases program" and cooperation "with other groups in stimulating public support in order that sufficient funds may be secured for the proper operation and maintenance of such activities." Under the provisions of the national mental health act, approved by President Truman last summer, $10,000,000 is appropriated for research throughout the country relating to psychiatric disorders and the development of more effective methods of prevention, diagnosis and treatment of such disorders. The fund will be distributed by the U. S. Public Health Service through grants-in-aid and otherwise. The members of the new committee are Drs. Oscar B. Biern, Huntington, chairman, and Albert L. Wanner, Wheeling; Joseph L. Knapp, Weston; Edward F. Reaser and George D. Johnson, Huntington, and Alfred A. Wilson, Oscar N. Morison, William B. Rossman and Newman H. Ryer, Charleston. Dr. Biern has been serving as chairman of the special psychiatric committee appointed several months ago, under the sponsorship of which psychiatric seminars were held in various cities of West Virginia. Dr. William M. Sheppe, Wheeling, is chairman of the new committee on the study and investigation of statistics concerning diabetes in West Virginia. The other members are Drs. Fred R. Whittlesey, Morgantown; William A. Thornhill, Charleston; Richard C. Neale, Bluefield, and L. Rush Lambert, Fairmont. The appointment of this committee will mean a closer relationship between the state medical association and the dietetic associations in the state.

WISCONSIN

Personal.—Mr. Robert O. McLean, Madison, assistant editor of the *Wisconsin Medical Journal*, has been appointed executive director of the Wisconsin division of the American Cancer Society.——Dr. and Mrs. George H. Williamson observed their fiftieth wedding anniversary in Neenah September 3.——Dr. Malcolm P. Andrews, Manitowoc, has accepted an appointment as resident physician at the Florida State College for Women, Tallahassee.——Dr. Robert C. Wolf, Hales Corners, has resigned, effective September 1, as health officer of the town of Greenfield, a post he held for ten years.——Dr. Drexel L. Dawson, Eau Claire, has been appointed chief medical officer of the Eau Claire district of the Veterans Administration. Dr. Dawson was a lieutenant colonel in the Medical Corps at the time of his separation from the service in 1946.

GENERAL

Orthopsychiatric Association.—Members of the American Orthopsychiatric Association, Inc., will meet in Cincinnati February 17-19 for the twenty-fourth annual meeting. The opening session will feature a symposium, "The Scientist in Society," with Rabbi Joshua Liebman presiding. For further information address Elizabeth Charleton, executive assistant, Room 916, 1790 Broadway, New York 19.

Free Blood Banks.—A blood bank service similar to the one that saved so many on the battle fields is now planned for peacetime activities of the American Red Cross. Blood banks are set up only on the request and in cooperation with established medical and health agencies. The Red Cross requires that hospitals and physicians make no charge to patients for blood given without charge by the volunteers.

Mid-Western Radiologists.—The Cleveland Radiological Society is sponsoring the seventh annual clinical conference of the Mid-Western Radiologists, which will be held in Cleveland February 14-15 at the Statler Hotel after a lapse of four years. Dr. Harry Hauser, Cleveland, is general chairman. Emphasis will be placed on the clinical aspects of problems of interest to radiologists, presented by leading men in the Cleveland area.

Gibbs Memorial Prize.—The New York Academy of Medicine, 2 East 103d Street, New York 29, has announced that $1,500 is available during 1947 under the Edward N. Gibbs Memorial Prize for original research in diseases of the kidney. Candidates must be physicians who have been graduated at least three years, be residents of the United States and submit evidence of research already performed and of facilities to prosecute research on the causation, pathology and new methods of treatment of diseases of the kidney. Applications with the required evidence should be addressed to the Gibbs Prize Committee at the New York Academy of Medicine prior to March 31.

Louis Livingston Seaman Fund.—The New York Academy of Medicine announces the availability of the Louis Livingston Seaman Fund for the furtherance of research in bacteriology and sanitary science. Two thousand five hundred dollars is available for assignment in 1947. This fund has been made possible by the terms of the will of the late Dr. Louis Livingston Seaman and is administered by a committee of the academy under the following conditions and regulations: 1. The committee will receive applications either from institutions or from individuals up to March 1, 1947. Communications should be addressed to Dr. Wilson G. Smillie, Chairman, Louis Livingston Seaman Fund, 1300 York Avenue, New York 21. 2. The fund will be expended only in grants in aid for investigation or scholarships for research in bacteriology or sanitary science. The expenditure may be made for securing technical help, aid in publishing original work or purchase of necessary books or apparatus.

Liquor Offenses and Driving While Intoxicated.—The official reports of the Federal Bureau of Investigation show, it is reported, that 1,228,150 arrests for liquor offenses were made in the year 1945 in 1,422 cities, a rate of 2,613.1 per hundred thousand of population in those cities. The number of arrests for liquor offenses in the year 1932 in 595 cities was 373,924, a rate of 1,726.3 per hundred thousand of population. The ratio of persons charged with driving while intoxicated in 1934 was 76.5 per hundred thousand in the total population of 793 cities, and in 1945 the ratio was 95.4 per hundred thousand of population in 1,422 cities having a total population of more than 47,000,000.

American Association for Advancement of Science Awards.—The 1946 $1,000 award of the American Association for the Advancement of Science has been divided, $500 going to Quentin M. Geiman, Ph.D., parasitologist, and Ralph W. McKee, Ph.D., biochemist, of the department of biological chemistry, Harvard Medical School, for their paper "Cultural Studies on the Nutrition of Malarial Parasites" and $500 to Tracy M. Sonneborn, Ph.D., professor of zoology, Indiana University, Bloomington, and co-workers of his department, Winifred Jacobson and Ruth B. Dipple, for their work on Paramecium aurelia, which was a study on the nature of the gene and its mechanism of action.

Unpublished German Medical Research.—Following six months' assignment in occupied Germany for the purpose of gathering manuscripts of medical and related research unpublished because of the war and postwar conditions, Dr. Hans Lowenback has resumed his work at Duke University Hospital, Durham, N. C., as associate professor of neuropsychiatry and physiology. While in Germany Dr. Lowenbach visited, under sponsorship of the Field Intelligence Agency Technical, schools in zones under United States, British and French occupation and in Berlin. More than 25,000 pages of original manuscripts were collected and microfilmed. Most of the papers contained research hitherto held secret under German wartime restrictions. This material is now on its way to this country to be catalogued and abstracted and will be immediately available to the public through the office of the Publications Boards, Department of Commerce, 16th and K streets, Washington 25, D. C.

Infant Mortality Rate Decreased.—Infant mortality declined further in 1946 from the low rate for 1945, the U. S. Public Health Service has announced. Provisional figures for the first ten months of 1946 indicate a decrease of 3.2 per cent from the rate for the same period of 1945. Final figures for 1945 released at this time show that the infant mortality rate of 38.3 deaths under 1 year per thousand live births was the lowest ever recorded for the United States. It is 3.8 per cent lower than the rate of 39.8 for 1944. Infant deaths numbered 104,684 in 1945. The maternal mortality rate of 2.1 per thousand live births for 1945 also showed a reduction of nearly 9 per cent from the rate of 2.3 for the previous year. The numbers of deaths from puerperal causes on which the maternal mortality rates are based were 5,668 and 6,369 respectively for 1945 and 1944. One factor contributing to the lower infant and maternal mortality rates is an increase from 1944 to 1945 in the proportion of babies delivered in hospitals; 78.8 per cent of all births registered in the United States were reported to have occurred in hospitals or other institutions in 1945.

Plotz Foundation Offers Grants for Research.—Twenty different research grants were given to institutions or investigators during 1946 by the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation. Applications for grants for 1947-1948 must be in the hands of the executive committee before April 15. Letters must state the qualifications of the investigator, accurate description of the research, the size of the grant requested and the specific use of the money to be expended. Applicants should also state whether or not they have approached other organizations for financial assistance and what other sources of support are relied on for research. Letters of recommendation are highly desirable. Applications should be addressed to Dr. Joseph C. Aub, Massachusetts General Hospital, Fruit Street, Boston 14. Maximum size of grants will usually be less than $500 to be used for research (1) directed toward the solution of problems of medicine or surgery or in branches of science bearing on medicine or surgery; (2) for the purchase of apparatus and supplies that are needed in special investigation and for the payment of unusual expenses incident to such special investigations but not for providing such materials that are normally part of laboratory equipment.

FOREIGN

Indian Journal of Radiology.—At the first Indian Congress of Radiology, Madras, recently the Indian Radiological Association authorized the publication of the *Indian Journal of Radiology* on a quarterly basis. The editors announce that they will appreciate receiving original articles or case reports for publication in the new journal. The editors are Drs. P. Rama Rau and K. M. Rai. The general secretary's office of the Indian Radiological Association is located at 155-157 Poonamallee High Road, Kilpauk, Madras.

International Congress of Obstetrics and Gynecology.—The International Congress of Obstetrics and Gynecology will be held in Dublin during the week beginning July 7 to celebrate the bicentennial of Rotunda Hospital. Representatives from all parts of the world will participate in the elaborate program. Dr. J. Hofbauer, Cincinnati, has accepted an invitation to be the official opening speaker on eclampsia. The program committee has chosen for discussion paramount problems of obstetrics. Messrs. Thomas Cook and Sons, Ltd., the authorized travel agency, will also accept registrations for the congress. The honorary secretary is Mr. G. F. Klingner, Rotunda Hospital, Dublin, Ireland.

Undergraduate Medical School Proposed.—The first undergraduate medical school in Palestine will be built under the joint auspices of the Hebrew University and Hadassah, Women's Zionist Organization of America, according to a statement of Eli Davis in the New York *Times*, November 22. Dr. Davis, who is deputy medical director of Hadassah in Jerusalem, is on a three month tour of American medical institutions to study methods. The new school will be built in Jerusalem on Mount Scopus adjoining the Hadassah Medical Center. It plans to admit 50 medical students next year and add 25 more dental and pharmacist studies. The new school will also make it possible to train 155 nurses instead of the 85 now being trained at the medical center. Eventually the capacity of the new school will be 400 students. Dr. Davis said the school will have a six year course with the possibility of extending it to seven years. One additional year of compulsory hospital residency will be required.

A Series of Abstract Journals.—Excerpta Medica, Inc., Amsterdam, is organizing and preparing a series of abstract journals covering the whole of medical science. These abstracts will be written in English and collected and edited in the Netherlands, but with the collaboration of a large number of specialists in other countries. The sections will be (1) anatomy, anthropology, embryology, histology; (2) physiology, biochemistry and pharmacology; (3) endocrinology; (4) microbiology and hygiene; (5) general pathology and pathologic anatomy; (6) internal diseases (also infectious diseases); (7) pediatrics; (8) neurology and psychiatry; (9) surgery (also orthopedics and urology); (10) obstetrics and gynecology; (11) otorhinolaryngology; (12) ophthalmology; (13) dermatology and venereology; (14) radiology, and (15) tuberculosis. Other sections may follow, as necessary, to meet specialist requirements. Chief editors of the *Excerpta Medica* are the professors A. P. H. A. de Kleijn, otorhinolaryngologist, M. W. Woerdeman, anatomist, and W. P. C. Zeeman, ophthalmologist, all at Amsterdam. The sections will be edited by section editors, experts in their fields in various countries, including the United States, assisted by responsible secretaries and by a large staff of technical assistants and linguists in addition to the commercial organizers and editors of the company. The first deliveries are promised in a few months' time and will continue at a rate once in a fortnight or monthly according to the volume of material. The Royal Netherlands Academy provides accommodation for all the books and periodicals abstracted in the *Excerpta*.

Marriages

Howard Franks Van Noate, Doylestown, Ohio, to Miss Marian Winifred Graham at Elkin, N. C., October 12.

Frank J. Moskal, Chicago, to Dr. Margaret I. Stemple of Morgantown, W. Va., November 28.

Alexander F. Thompson, New York, to Miss Helen Battle of Rocky Mount, N. C., September 11.

Stephen T. Whelan, Philadelphia, to Miss Virginia King Ball of Chestnut Hill, Pa., August 3.

Edward L. Waisbrot to Miss Janet Ginsburg, both of Canton, Ohio, November 30.

Joseph Warren West, Owego, N. Y., to Miss Jane McCay of Miami, Fla., October 13.

Deaths

Christopher Charles Beling ⊕ Newark, N. J.; born in Colombo, Ceylon, April 4, 1873; L.R.C.S. in Edinburgh, Scotland, in 1900; at one time connected with the government medical service of India; served as house surgeon of the government Civil Hospital at Colombo; came to the United States in 1900; appointed in 1901 to the staff of the New Jersey State Hospital for the Insane at Greystone Park; served as clinical assistant at the Vanderbilt Clinic in New York and as chief of the Neurological Clinic of the Newark City Dispensary; in 1908 was appointed attending neurologist and placed in charge of the first psychiatric clinic in New Jersey at St. Michael's Hospital in Newark; served as chief of the neuropsychiatric department of the Newark City Hospital; consulting neurologist or psychiatrist to the Essex County Hospital, Cedar Grove, New Jersey State Village for Epileptics at Skillman, Hospital of St. Barnabas, Presbyterian Hospital and Newark Eye and Ear Infirmary in Newark, Mountainside Hospital, Montclair, West Hudson Hospital, Kearny, Hackensack (N. J.) Hospital, Somerset Hospital, Somerville, Morristown (N. J.) Memorial Hospital, Newton (N. J.) Memorial Hospital and Monmouth Memorial Hospital, Long Branch; past president of the Morris County Medical Society; member, judicial council, since 1912 and chairman, committee on medical defense, since 1922, Medical Society of New Jersey; since 1912 charter member, Academy of Medicine of Northern New Jersey; member, New York Academy of Medicine, New York Neurological Society, New Jersey Neuropsychiatric Association, of which he had been president and councilor, British Medical Association, American Neurological Association, American Psychiatric Association, Association for Research in Nervous and Mental Diseases and the Society for Relief of Widows and Orphans of Medical Men of New Jersey, of which he had been a trustee since 1920; fellow of the American College of Physicians; founded the first juvenile clinic and bureau of mental hygiene in Newark; director of the bureau from 1919 to 1922; died in Montclair Nov. 30, 1946, aged 73, of hypertensive heart disease.

William Daniel Yavorsky ⊕ Commander, M. C., U. S. Navy, Cedar Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1935; interned at the Jersey City Hospital in Jersey City; took postgraduate work at the New York Polyclinic and affiliated hospitals and the Universities of Budapest and Debrecen in Hungary; commissioned a lieutenant (jg) in the U. S. Naval Reserve; later commissioned in the regular navy; shortly after the attack on Pearl Harbor was sent into the Pacific area, where he rendered distinguished service as commander of a naval hospital unit; during fourteen months' service in the Pacific area was awarded a number of citations, including a presidential citation; returned to the United States in 1943 and was again sent to the Pacific area in 1944, returning to the United States in 1945; during the atomic bomb tests in 1946 at Bikini he was chief medical officer aboard the carrier *Boxer*; died in the Naval Hospital, Oakland, Oct. 18, 1946, aged 36, of poliomyelitis.

Alfred Lee Briskman ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1927; fellow of the American College of Physicians; past president of the Colorado Tuberculosis Association; interned at the Ancon Hospital in Ancon, Canal Zone; lecturer to nurses at the Seton School of Nursing at Glockner Sanatorium and Hospital in Colorado Springs; resident chief physician, Union Printers Home and Tuberculosis Sanatorium, in Colorado Springs from 1929 to 1944, when he resigned to become medical director of the Jewish Consumptives' Relief Society Sanatorium in Spivak; died in Colorado Springs, Colo., Nov. 26, 1946, aged 44, of hypertension and cerebral thrombosis.

Perthas Calvert Chenoweth ⊕ Grafton, W. Va.; Emory University School of Medicine, Atlanta, 1928; served a residency at the Southside Community Hospital in Farmville, Va.; began active duty as a captain in the medical corps, Army of the United States, in July 1942, serving as a surgeon in the North African and Italian campaigns and was stationed at hospitals in the front lines in these theaters; honorably discharged in September 1945; member of the West Virginia Gynecological and Obstetrical Society; formerly on the staff of the Golden Clinic, Davis Memorial Hospital, in Elkins; died Nov. 25, 1946, aged 45, of pulmonary embolism following a cholecystectomy.

Robert Van Valzah ⊕ Goby, Va.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; fellow of the American College of Physicians; chairman of medical advisory board number 13, Selective Service, U. S. Army, during World War I; specialist certified by the American Board of Internal Medicine; served as professor of medicine at the University of Wisconsin Medical School in Madison, where he had been physician to the State of Wisconsin General Hospital from 1925 to 1935; author of a chapter on "Diseases Due to Rickettsiae" in Musser's Internal Medicine; died Nov. 23, 1946, aged 64, of cardiac failure.

Kenneth Earle Lowman ⊕ Medical Director, Captain, U. S. Navy, Coronado, Calif.; born in Orangeburg, S. C., Feb. 23, 1890; Medical College of the State of South Carolina, Charleston, 1916; fellow of the American College of Surgeons; entered the U. S. Navy in 1917; senior surgeon on Admiral Thomas Hart's staff; formerly prisoner of war held by the Japanese; rescued in Mukden in 1945 and later assigned to duty on the retiring board of the Naval Hospital in San Diego; served on the old carrier *Saratoga;* died in Lake Henshaw, Oct. 26, 1946, aged 56, of an accidental gunshot wound while duck hunting.

Thomas Joseph Ball, Cambridge, Mass.; Harvard Medical School, Boston, 1887; instrumental in the founding of the Holy Ghost Hospital; died in the Cambridge City Hospital Nov. 12, 1946, aged 87.

Williston Wright Barker ⊕ Boston; Harvard Medical School, Boston, 1906; member of the New England Pediatric Society; affiliated with the Faulkner Hospital and the Evangeline Booth Maternity Hospital and Home; died Nov. 26, 1946, aged 64, of carcinoma.

Mott Parks Blair, Marshville, N. C.; Medical College of Virginia, Richmond, 1895; member of the American Medical Association; died Nov. 28, 1946, aged 79, of coronary thrombosis.

Dennis J. Borders, Redbud, Ga.; Atlanta Medical College, 1895; died Nov. 4, 1946, aged 73, of cerebral hemorrhage.

Charles Newton Brooks, East St. Louis, Ill.; Jenner Medical College, Chicago, 1910; Chicago College of Medicine and Surgery, 1912; died in St. Clair County Hospital, Belleville, Nov. 27, 1946, aged 71.

John Oliver Cook, Savannah, Ga.; University of Virginia Department of Medicine, Charlottesville, 1897; served during World War I; lieutenant colonel in the medical reserve corps, not on active duty; formerly affiliated with the Hospital for Epileptics and School for Feebleminded in Woodward, Iowa; died in the United States Marine Hospital Oct. 10, 1946, aged 71, of coronary thrombosis.

Arthur Garfield Cosby, Fountain Run, Ky.; St. Louis College of Physicians and Surgeons, 1922; member of the American Medical Association; died Nov. 18, 1946, aged 62.

George Dart Crossette, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1904; served as police surgeon; died in Morris, Minn., Nov. 29, 1946, aged 65, of angina pectoris.

Alexander J. De Grand, Chicago; Chicago College of Medicine and Surgery, 1916; member of the American Medical Association; died Nov. 18, 1946, aged 61, of chronic myocarditis.

John D. England, Axtell, Neb.; Bellevue Hospital Medical College, New York, 1887; president of the Farmers & Merchants Bank; died in November 1946, aged 88.

Clyde Mulhallon Fish ⊕ Pleasantville, N. J.; Jefferson Medical College of Philadelphia, 1897; member of the American College of Chest Physicians; fellow of the American College of Physicians; past president of the Atlantic County Medical Society; medical director of the Atlantic County Hospital for Tuberculous Diseases at Northfield; consultant in diseases of the chest and chief of the tuberculosis clinic at the Atlantic City Hospital, where he died Nov. 21, 1946, aged 71, of intracranial hemorrhage and multiple myeloma.

James Jerdan Fraley, Hominy, Okla.; Memphis (Tenn.) Hospital Medical College, 1903; served as mayor; died Nov. 10, 1946, aged 69, of cerebral thrombosis.

Joseph Witter Godfrey, Swampscott, Mass.; College of Physicians and Surgeons, Boston, 1890; member of the American Medical Association; past chairman of the school committee; vice president of the Union Hospital in Lynn, where he died Nov. 27, 1946, aged 79, of carcinoma of the liver.

Mark Joseph Haley, Margate City, N. J.; Maryland Medical College, Baltimore, 1911; died in the Atlantic County Hospital for Mental Diseases in Northfield Nov. 28, 1946, aged 67, of cerebral hemorrhage.

Joseph Underwood Hall, San Francisco; Jefferson Medical College of Philadelphia, 1889; fellow of the American College of Surgeons; formerly on the staff of the O'Connor Sanitarium in San Jose, Calif.; served during World War I; died Oct. 25, 1946, aged 78.

Edward H. J. Hennessey, Stratford, Conn.; University of Maryland School of Medicine, Baltimore, 1912; member of the American Medical Association; served during World War I; on the staffs of the Bridgeport Hospital and St. Vincent's Hospital in Bridgeport, where he died Nov. 1, 1946, aged 59.

John Samuel Hickman ⊕ Jamestown, N. Y.; Northwestern University Medical School, Chicago, 1915; fellow of the American College of Surgeons; served during World War I and later as a captain in the medical corps of the regular army, serving as flight surgeon in the air corps at Chanute Field, Rantoul, Ill.; chairman of the health and hospital board; on the staffs of the Jamestown General and Woman's Christian Association hospitals; died Nov. 11, 1946, aged 59.

Henry M. Hittner, Kansas City, Mo.; Rush Medical College, Chicago, 1893; died in Trinity Lutheran Hospital Oct. 21, 1946, aged 75, of coronary occlusion and hypertension.

Leslie W. Jones, Chicago; Chicago Homeopathic Medical College, 1897; died in the Loretto Hospital Nov. 28, 1946, aged 74, of a skull fracture received when struck by an interurban bus.

Joseph Abraham Koppel ⊕ Jersey City, N. J.; University of Wooster Medical Department, Cleveland, 1904; died Nov. 1, 1946, aged 68, of coronary occlusion.

Hugh Franklin Littell, Dayton, Ohio; Cleveland Medical College, Homeopathic, 1896; served as a member of the board of education; died Nov. 25, 1946, aged 86, of heart disease.

John Fredrick Martin, Stillwater, Okla.; University Medical College of Kansas City, Mo., 1905; member of the American Medical Association; died Oct. 31, 1946, aged 70.

Charles Russell Morgan ⊕ Boston; Tufts College Medical School, Boston, 1907; formerly an officer in the U. S. Navy; served during the Boxer Rebellion, in the Mexican Border War and in the Massachusetts National Guard; on the courtesy staffs of the Lawrence Memorial Hospital at Medford, Mass., Winchester Hospital at Winchester and the Symmes Hospital in Arlington; died Nov. 28, 1946, aged 68, of coronary occlusion.

Allen Thomas Moulton, Boston; University of Maryland School of Medicine, Baltimore, 1911; member of the American Medical Association; served overseas during World War I; for many years affiliated with the Cambridge City Hospital in Cambridge, Mass., Carney Hospital and Boston Dispensary; died in the Peter Bent Brigham Hospital Nov. 22, 1946, aged 56, of cardiac hypertrophy and pulmonary fibrosis.

Charles Miller Murry, Ripley, Miss.; Jefferson Medical College of Philadelphia, 1890; member of the American Medical Association; formerly member of the state board of health; for many years health officer of Tippah County; died Nov. 6, 1946, aged 78.

Patrick Eugene Nagle, St. Louis; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880; died in the De Paul Hospital Nov. 1, 1946, aged 94, of prostatitis.

Earl Palmer ⊕ Logansport, Ind.; Rush Medical College, Chicago, 1906; formerly affiliated with the Northern Indiana Hospital for Insane; died in the Cass County Hospital Nov. 24, 1946, aged 64, of cardiovascular renal disease.

Fred Beverly Pickerel ⊕ Cincinnati; University of Cincinnati College of Medicine, 1921; interned at the Cincinnati General Hospital; member of the Cincinnati Academy of Medicine; on the staff of the Christ Hospital, where he died Nov. 15, 1946, aged 50, of coronary occlusion.

Milton Hickox Prosperi ⊕ Washington, D. C.; George Washington University School of Medicine, Washington, D. C., 1904; died Nov. 11, 1946, aged 68, of coronary occlusion.

Thomas Neely Reid, Matthews, N. C.; University of the City of New York Medical Department, 1891; honorary member of the Medical Society of the State of North Carolina; member of the American Medical Association; on the staff of the Presbyterian Hospital in Charlotte; died in the Mercy Hospital, Charlotte, Nov. 28, 1946, aged 78, of coronary occlusion.

George N. Seidlitz, St. Louis; the Hahnemann Medical College and Hospital, Chicago, 1884; Homeopathic Medical College of Missouri, St. Louis, 1884; formerly professor of ophthalmology and otology at the Homeopathic Medical College of Missouri; member of the American Medical Association; served on the staff of Christian Hospital, where he died Nov. 5, 1946, aged 85, of coronary thrombosis.

Wilfrid Dooris Sharp ⊕ Cleveland; Starling Medical College, Columbus, 1904; member of the Academy of Medicine of Cleveland and the Cleveland Medical Library; on the courtesy staff of the Glenville Hospital; died in the Cleveland Clinic Hospital Nov. 5, 1946, aged 65, of gastric hemorrhage and lymphosarcoma.

Samuel Anise Shoemaker, Orlando, Fla.; Medical College of Indiana, Indianapolis, 1898; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; died in Muncie, Ind., Nov. 6, 1946, aged 80.

Francis Jerome Short, Jersey City, N. J.; Georgetown University School of Medicine, Washington, D. C., 1904; for many years police surgeon; on the staff of St. Francis Hospital; died Nov. 4, 1946, aged 65.

Richard Curtis Smith ⊕ Drew, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; past president of the Delta Medical Society, school board and Rotary Club; past vice president of the Merchants' and Planters' Bank, of which he was director; past member of the board of aldermen; died in the King's Daughters' Hospital, Greenville, Nov. 7, 1946, aged 70, of heart disease.

Philip Srebnik, New York; Long Island College Hospital, Brooklyn, 1909; died Nov. 12, 1946, aged 62, of coronary arteriosclerosis.

Charles Tiffany St. Clair, Bluefield, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1896; fellow of the American College of Surgeons; member of the American Academy of Ophthalmology and Oto-Laryngology; specialist certified by the American Board of Otolaryngology; past president and secretary of the Virginia Society of Ophthalmology and Otolaryngology; died Nov. 17, 1946, aged 73, of heart disease.

Jonas Wakefield Stitzel, Hollidaysburg, Pa.; Hahnemann Medical College and Hospital, Philadelphia, 1896; died Nov. 13, 1946, aged 78, of chronic nephritis.

Charles Judson Tomer, Corning, N. Y.; University of the City of New York Medical Department, New York, 1887; served as city physician and county coroner; at one time connected with the Steuben Sanitarium, Hornell; died Nov. 5, 1946, aged 82.

Edwin James Glass Valentine Jr., Shelbyville, Ind.; New York Homeopathic Medical College and Flower Hospital in New York, 1933; member of the American Medical Association; interned at the Muhlenberg Hospital in Plainfield, N. J.; at one time plant physician for the E. I. du Pont de Nemours & Company in Charlestown; died in St. Francis' Hospital, Jersey City, Nov. 16, 1946, aged 44, of acute nephritis.

John William Wallace, Johnson City, Tenn.; Tennessee Medical College, Knoxville, 1892; member of the American Medical Association; served overseas during World War I; died in San Francisco Nov. 8, 1946, aged 76, of cholecystitis.

James L. Weddington ⊕ Hendersonville, N. C.; Southern Medical College, Atlanta, 1898; past president of the Henderson County Medical Society; on the staff of the Patton Memorial Hospital; died Nov. 6, 1946, aged 70, of heart disease.

Clifford Charles Wehn ⊕ Rockford, Ill.; Chicago College of Medicine and Surgery, 1914; served during World War I; died in St. Anthony's Hospital Nov. 15, 1946, aged 58, of coronary sclerosis.

Richard Frank Werner, Eau Claire, Wis.; Rush Medical College, Chicago, 1899; member of the American Medical Association and in 1911 a member of its House of Delegates; served on the staff of the Luther Hospital; died in Rochester, Minn., Nov. 24, 1946, aged 72, of myocardial infarction.

Alfred D. Wilkinson, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C., 1893; formerly associated with the U. S. Pension Bureau and the Veterans Administration; died Nov. 14, 1946, aged 84, of cirrhosis of the liver and hypertension.

Lester Leo Williams ⊕ El Dorado, Kan.; Washington University School of Medicine, St. Louis, 1920; on the staff of the Susan B. Allen Memorial Hospital; died near Thatcher, Colo., Nov. 4, 1946, aged 51, of coronary occlusion.

Oscar Hermon Wilson, Ivyland, Pa.; Jefferson Medical College of Philadelphia, 1906; died Nov. 1, 1946, aged 66, of heart disease.

Graven Fields Winslow ⊕ White Plains, N. Y.; University of Virginia Department of Medicine, Charlottesville, 1924; fellow of the American College of Surgeons; served during World War I; interned at the Manhattan Eye, Ear and Throat Hospital in New York and the University of Virginia Hospital in University, Va.; served as consulting surgeon, Country Branch of New York Orthopedic Dispensary and Hospital; on the staff of the White Plains Hospital, where he died Nov. 13, 1946, aged 54, of coronary thrombosis.

Calvin Lee Woolsey, Braymer, Mo.; St. Louis University School of Medicine, 1906; member of the American Medical Association; died in November, aged 62, of coronary thrombosis.

Foreign Letters

Jan. 18, 1947.

The Controversy on the National Health Service

The final figures of the plebiscite of the whole profession, taken by the British Medical Association on the question whether to negotiate or not with the minister of health on the working of the National Health Service, have been declared. They show that 81 per cent of civilian practitioners voted and that of those who voted 45.5 per cent voted Yes and 54.5 per cent No. The representative body of the British Medical Association will meet on January 28 to decide what course shall be taken by the association. The presidents of the three Royal Colleges—of Physicians, of Surgeons and of Obstetrics and Gynecology—have now intervened by sending a joint letter to the minister of health, Mr. Bevan. They state that the opposition of a substantial part of the medical profession to renewal of discussions with the government regarding the National Health Service causes them concern. They recognize that certain of the principles of the service are incorporated in the act but that there are other issues of importance which will be determined by regulations, on which the form of the service will largely depend. They feel that there is an opportunity in framing the regulations to meet several of the objections of the profession. Moreover, the implications of some of the proposals for the service are not clear to the profession, and their clarification would be helpful. They hope, therefore, that the minister will clarify the following points and give an assurance that he will endeavor, within the framework of the act, to meet the views held so strongly by many practitioners.

The first point is a general one. They believe that behind the opposition is the fear that to enter into discussions would compromise the position of doctors by implying their approval of the main provisions of the act. In the general practitioners' part of the service the presidents find three points on which they think that a statement from the minister would be helpful. First, the method of remuneration is left to be dealt with by regulations. The minister has made clear his preference for a basic salary, apparently making it generally applicable because of difficulties in particular cases. It is agreed that there are circumstances in which a basic salary or a guaranteed minimum may be necessary, but this is not regarded as justifying a universal basic salary. Cannot the circumstances in which a basic salary is appropriate be left open for discussion? Secondly, a large element in the opposition of some practitioners is the fact that if the tribunal recommends the expulsion of a practitioner from the service his appeal is to be judged by the minister who has appointed two of the three members of the tribunal. Neither the words nor the spirit of the act prevent the minister from agreeing to seek the advice of the General Medical Council (the body which normally maintains professional discipline). In the third place there is a widespread fear that there will be serious interference with the liberty of movement of practitioners. It would be useful if the minister would explain how he anticipates that this part of the act will work, with particular reference to partnerships and groups. Among specialists there are also grounds for anxiety. As in the case of general practitioners there is the general issue of the freedom of the profession and the availability to the people of independent medical advice. The whole profession regards it as essential that independent practice should continue. The assurance that independent practitioners would be free to remain in attendance on their patients when admitted to the private wings of hospitals and also that consultants holding honorary positions on the staffs of hospitals would be free to use all the facilities provided had been gladly received.

In reply to the presidents' letter, the minister of health said that there was no ground for the fear that entering into discussion would compromise the position of the doctors. For them the issue was whether they would accept or forego the opportunity to influence the shaping of the service. He wanted their help and advice in this task. He denied the allegation that he had been unwilling to negotiate with the profession. Discussion had taken place, but this had necessarily been conditional, as he could not publish proposals before they had been submitted to Parliament. Nevertheless he and his officers had full discussions with the representatives of the profession. He then dealt with the specific points raised. The government had always accepted the view of the profession that remuneration should substantially be based on capitation fees but should include an element of salary. There were circumstances in which a guaranteed minimum was necessary, but he would like to discuss this with the profession. He was willing to discuss the second point with representatives of the profession. It was not true, as had been said, that doctors would become civil servants. Their full civic rights were preserved unimpaired. As to liberty of movement, there was no power to direct a doctor to go anywhere or to do anything, though there was a provision to avoid undue concentration of doctors in any one area. A doctor who desired to enter the service in a new area would have to obtain the approval of the central committee of nine, seven of whom would be medical practitioners appointed after consultation with the medical profession. In the case of a partnership the members would have the initiative in selecting a doctor. As to specialists, there would be no interference with clinical freedom, and it was a basic principle of the service that doctors engaged in independent specialist practice and that specialists should be free to continue and to remain outside or join the service as they wished. They would be able to treat their private patients in the private beds of their own or other hospitals subject to availability. The details of all these arrangements needed to be discussed with the profession.

The Difficulty of Finding a Cure for the Common Cold

The attempt to find a cure for the most prevalent of all diseases, the common cold, is proving very difficult. A research on the subject, described as a combined operation of the Medical Research Council and the Ministry of Health, has been proceeding for nearly a year. It was said that promising results were being obtained by the Common Cold Research Unit of the National Institute for Medical Research, but a warning was given against any optimistic notion that a cure for colds could be discovered without much more research. The importance of the problem is shown by the statements of Dr. W. H. Bradley, senior medical officer of the infectious diseases division of the Ministry of Health, that the total annual cost to the nation of upper respiratory infections is 40 million man days and that there occurs an average of three and one half attacks per person. Other disclosures were that attempts to grow the responsible virus in culture had not succeeded and that there was no hope of photographing the virus with the electronic microscope until large quantities had been obtained in isolation. Similar experiments were contemplated in America.

Dr. C. H. Andrewes of the Medical Research Council, who is in charge of the present investigation, states that the good progress made in recent years in work on influenza was largely due to the discovery in 1933 that ferrets could be infected with the disease. He is sure that corresponding advances could be made in the investigation of the common cold if a susceptible laboratory animal could be found. The only known laboratory

become sufficiently common it would entail double administration, a further growth of social bureaucracy and a further removal of people from production at a time when thousands of men are needed for keeping the wheels of production turning.

There is another typical Social Democratic touch to this proposal, which is sure to become a law this year. At a time of an acute shortage of physicians, with the hospital corridors crowded with patients, and druggists working to the point of exhaustion, when in fact all medical facilities are being greatly strained as a result of the disproportion between supply and demand, this plan of hospitalization for all citizens in 1950 becomes somewhat of a grim joke, especially since the minister of commerce has succeeded in tying up a goodly share of Sweden's productive resources for the use of Russia for the next ten years. No one has as yet furnished a clear idea of how this trick of lifting oneself by the hair is to be accomplished, and only time will tell how this latest social reform will work out.

Proposal to Shorten Medical Schooling

Although the number of doctors per inhabitant is higher in Sweden than in many other countries, at present there is, as everywhere, a great shortage of physicians and there promises to be an even greater deficiency as new hospitals are built and new forms of social medicine develop. The Swedish Medical Board published a report recently in which it stressed the advisability of increasing the number of medical students immediately as much as possible. Unfortunately, the country's largest medical school is unable to accept even a third of those applying for entrance. An additional medical school is badly needed, for only 185 students are now able to enter the schools each year, while at least 300 are needed to fill future demands. With such an increase Sweden would have the same relative number of physicians as Norway, i. e. one per thousand inhabitants, but still not as many as Britain and Denmark. On the basis or reports from the United States and England it is now proposed that the overall period of study be shortened in an effort to produce more doctors faster, but this is a step needing much consideration and discussion in a conservative country like Sweden.

Physicians' Strike Settled

The threatened strike of physicians at two of Stockholm's largest hospitals was called off at the very last minute. The proposal made by the committee appointed to study the situation was accepted. Resident physicians are now permitted to charge fees for all the extra paper work they have to do, such as making out special certificates. However, they are no longer to be regarded as civil servants and therefore are not entitled to the advantages pertaining thereto, such as family pensions. Therefore the settlement of the strike was only semisatisfactory for the doctors, who although they do not wish to be civil servants, had hoped to retain the pensions. The formation of a new committee to investigate further the entire setup has been approved by the government and new changes are to be expected in time.

Aviation Medicine

A committee for the study of aviation medicine was recently established in Sweden with Professor G. Kahlson of Lund University as chairman. The committee is to take the initiative in research in aviation medicine, one of its first jobs being to work on the medical problems contributing to flying accidents and safety. Three laboratories have been set up, at the University of Lund, at the Caroline Institute and at the Institute of Physical Culture. "One would think it unnecessary," said Professor Kahlson, "to carry on independent research in Sweden in a subject which has been and is being so thoroughly covered by the British and Americans, not to mention the Russians. Unfortunately, however, the most important results achieved in those countries are still kept secret and we must therefore do our own research and no longer wait for information from other sources."

First Swedish Industrial Disease Clinic

The Swedish Medical Board has proposed the establishment of a badly needed clinic for industrial diseases at Caroline Hospital, which would be the first in Sweden. It is claimed that with all the new industries bringing with them new dangers to health, the time is definitely ripe for a central organization for the investigation of and research into industrial disease occurring throughout the country. A hospital is also planned in conjunction with the experimental body, with beds for about 25 patients.

Poliomyelitis Vaccine

A recent report published by Professors The Svedberg and Arne Tiselius and Dr. S. Gard stated that considerable progress has been made by investigators at Uppsala in the production of a poliomyelitis vaccine. Their experiments with mice have been successful in producing resistance against the disease. The work at Uppsala has been made possible through grants from King Gustav V's 80th Birthday Fund. By the beginning of 1948 it is hoped that King Gustav's Research Institute will be completed in Uppsala at a cost of 1.3 million kronor for the building and 200,000 kronor for the equipment. Various other foundations have contributed to the cost of an electron microscope and other special apparatus.

Influenza Vaccine

A vaccine against influenza is soon to be made in Sweden at the government bacteriological laboratory. Preparatory experiments have already been made and, as soon as a centrifuge ordered from the United States arrives, production is to begin on a large scale. The Swedes are still doubtful about the effectiveness of the vaccine but hope, as soon as more of the preparation becomes available, to determine on the basis of their own research just how satisfactory it is.

Russian Visitors to Stockholm

Several well known Russian physicians arrived in Stockholm recently, and more are to be expected. Professor Egorov, a prominent Soviet brain surgeon, Professor Anatole Frumkin, specialist in renal surgery, and Professor Holdin, cancer scientist, have already arrived. The Russians are guests of Caroline Institute; they will visit and study that institution and also hold lectures on their own experiences in medicine.

Scandinavian Cooperation in Research

Fourteen laboratories in the Scandinavian countries are combining their efforts in an extensive common program to study the thyroid hormones in order to determine the exact effective strength of thyroid gland preparations, according to Dr. Håkan Rydin, chairman of the Nordic committee which recently held a two day meeting in Stockholm. Fourteen pharmaceutical laboratories are working on the same problems and sharing experiences and results, thus saving much duplication of time and effort. The results of their experimentation will be published at the next meeting, scheduled to be held in Norway in the spring.

Death of Ole Chievitz

Professor Ole Chievitz, chief surgeon of the Finsen Institute, died recently at the age of 63. During the German occupation of Denmark he was known as one of the most energetic members of the resistance movement and was twice arrested by the Nazis. He was also of great assistance to Finland and was leader of the Red Cross ambulance unit that went to that country in 1918 and 1939. During the summer of 1941 he worked as a volunteer field surgeon in Finland until the Finnish troops reached the old border.

animal which can be infected with the common cold is the chimpanzee, which is expensive, scarce and difficult to handle. The need is for normal persons between the ages of 18 and 40 who are willing to accept the gentle discipline imposed during the tests of living in isolation, except for one partner, for ten days in the hospital. In his aim to establish a national panel of volunteers, Dr. Andrewes has invited the cooperation of business houses, who lose hundreds of pounds yearly in consequence of colds.

Treatment of Kala-Azar

At a recent meeting of the Medical Society of the Paris Hospitals P. Durand, P. Benmussa and Caruand of Tunis reported their results in 6 cases treated with antimoniate of N-methyl glucamine, a new French antimony compound. They use it in a 30 per cent solution by intramuscular injections, 0.5 to 2 cc. for young children and 1 to 3 cc. for grown up children and adults in a series of fifteen injections three times a week; toleration is perfect even by young children. In the *Presse médicale* Paul Giraud and René Bernard of Marseilles set forth the good results they obtained with the same drug in 4 cases of kala-azar. Moreover, the authors praise a product called "diamidine," not yet on the market; it is 4-4 diamidino-diphenoxypentane, a powder which they use intramuscularly in a solution of 2 per cent, beginning with 0.5 cc. for the first two or three injections and going up to 2 cc. for young children and to 3 to 5 cc. for grown up children and adults. They make series of twelve to fifteen injections three times a week, with intervals of two to three weeks between the series. The results are excellent, the fever decreases rapidly, the volume of the spleen diminishes, and after two to three series the general condition improves. The death rate, which up to the present has been 10 to 15 per cent, tends to become nil.

Penicillin in Otorhinolaryngology

Leroux-Robert and Bezard stated that it is not otitis and mastoiditis which give the indication for penicillinotherapy but, and above all, their complications. Through it these investigators obtained splendid results in oculo-orbital accidents, ethmoiditis, osteomyelitis of the bones of the face, infantile suffocating and ulcerous laryngitis, and the plastic surgery of the face. They observed the cure of 4 cases of cavernous phlebitis, 2 cases of otogenic septicemia and 9 of confirmed meningitis. Lafitte-Dupont reported a cure of mastoiditis complicated with phlebitis of the sinus, meningitis and septicemia. Binet of Bourges obtained 85 per cent of cures in abscess of the brain through local penicillinotherapy without drainage by employing puncture and injecting penicillin afterward. Piquet had very good results by filling the cavity with sulfamidopenicillin powder.

A New Pharmacoradiographic Agent

In the *Archives de l'apparcil digestif* Guy Albot, Jacqueline Renaux and Emile Girard report experiments with intravenous insulin, which they use to get x-ray films of the pyloric niches, of the small prepyloric curvature or in duodenal tuberculosis. Up to now, morphine has been used for this purpose (Porcher's method). The authors inject 10 international units of insulin fifteen minutes before the absorption of the barium. After a short latent phase, slow and deep contractions are noted, and a large dilatation of the bulb and of the duodenum occurs; within five to six minutes more than the half of the meal is evacuated. Immediately after the examination the patient is given sugar by mouth, which makes all uncomfortable sensations disappear, sensations which are far less uncomfortable than those caused by morphine.

The Stability of Penicillin Solutions Treated with Formaldehyde

At a recent meeting of the Academy of Medicine G. Ramon and R. Richou reported the results of experimental research on the antibiotic properties of penicillin solutions treated with formaldehyde. They found that 0.03 to 0.1 per cent of the commercial solution does not diminish sensibly the antibiotic power of penicillin in solution. The solutions of penicillin so treated, or with formaldehyde and simultaneously heated at 55 C. proves relatively stable. These solutions can be kept in a cool room (+ 2 to + 4 C.) during three months or at a temperature of + 15 to + 20 C. during one month. These results, which have to be submitted to clinical control, may be of great clinical interest.

Medical Students in Paris

Among the 45,414 students of the Paris University in 1946 there were 8,209 at the Faculty of Medicine and 2,452 at the Faculty of Pharmacy. Among the medical students, there were 6,192 French boys and 1,721 French girls, 162 foreign boys and 26 foreign girls, 102 students of the overseas territories and 6 girls of the same origin. At the Faculty of Pharmacy there were 1,084 French boys, 1,323 French girls, 15 foreigners and 30 students of the overseas territories.

Congress of the French Society of Otorhinolaryngology

The forty-fourth Congress of the French Society of Otorhinolaryngology convened in Paris on the 21st of October under the presidency of André Moulonguet and was attended by a large number of French and foreign specialists.

SWEDEN

(From Our Regular Correspondent)

STOCKHOLM, *Jan. 4, 1947.*

Free Medical Care from 1950

Social reforms come thick and fast in Sweden now that the Social Democrats, judging from the trend of recent elections, feel some of their power slipping away. Last year a new complex of old age pensions was passed by the Riksdag, and before that body convened for the Christmas holiday the social minister presented his much debated proposal for general sickness insurance. The new legislation, to become effective July 1, 1950, includes free hospitalization for all, certain prescribed medicines at no cost, and others at half cost. All Swedes are to be compelled to be insured, and in their insurance benefits are to be included, in addition to the foregoing, compensation for doctor's care and travel expenses to the doctor. Adults are to receive a sickness benefit of 3.50 kronor a day, while adolescents and pensioners are to get 2 kronor and housewives 1.50 kronor a day. To this is added a child benefit of 0.50 kronor per child a day. The compulsory insurance does not do away with the voluntary insurance plans which give daily benefits of 1.50, 3 and 4.50 kronor. The combined maximum benefits under the plan will thus be 8 kronor a day for single persons and 10 kronor for married persons without children. The cost of the compulsory insurance will be 24 kronor a year for a daily benefit of 3.50 kronor and 16 kronor for a daily benefit of 2 kronor. These costs are to be added to the tax bill.

The debate has raged chiefly on the question of uniform versus graded daily benefits in the compulsory insurance, and the minister's plan passed the committee by a narrow margin. The most serious criticism leveled against the uniform minimum benefit of 3.50 kronor a day is that it is quite insufficient to cover the fixed daily cost of living of the majority of wage earners, who would need to supplement it with voluntary insurance in order to cover their economic commitments during a few weeks of sickness. Should this necessary supplement become sufficiently common it would entail double administration, a further growth of social bureaucracy and a further removal of people from production at a time when thousands of men are needed for keeping the wheels of production turning.

There is another typical Social Democratic touch to this proposal, which is sure to become a law this year. At a time of an acute shortage of physicians, with the hospital corridors crowded with patients, and druggists working to the point of exhaustion, when in fact all medical facilities are being greatly strained as a result of the disproportion between supply and demand, this plan of hospitalization for all citizens in 1950 becomes somewhat of a grim joke, especially since the minister of commerce has succeeded in tying up a goodly share of Sweden's productive resources for the use of Russia for the next ten years. No one has as yet furnished a clear idea of how this trick of lifting oneself by the hair is to be accomplished, and only time will tell how this latest social reform will work out.

Proposal to Shorten Medical Schooling

Although the number of doctors per inhabitant is higher in Sweden than in many other countries, at present there is, as everywhere, a great shortage of physicians and there promises to be an even greater deficiency as new hospitals are built and new forms of social medicine develop. The Swedish Medical Board published a report recently in which it stressed the advisability of increasing the number of medical students immediately as much as possible. Unfortunately, the country's largest medical school is unable to accept even a third of those applying for entrance. An additional medical school is badly needed, for only 185 students are now able to enter the schools each year, while at least 300 are needed to fill future demands. With such an increase Sweden would have the same relative number of physicians as Norway, i. e. one per thousand inhabitants, but still not as many as Britain and Denmark. On the basis or reports from the United States and England it is now proposed that the overall period of study be shortened in an effort to produce more doctors faster, but this is a step needing much consideration and discussion in a conservative country like Sweden.

Physicians' Strike Settled

The threatened strike of physicians at two of Stockholm's largest hospitals was called off at the very last minute. The proposal made by the committee appointed to study the situation was accepted. Resident physicians are now permitted to charge fees for all the extra paper work they have to do, such as making out special certificates. However, they are no longer to be regarded as civil servants and therefore are not entitled to the advantages pertaining thereto, such as family pensions. Therefore the settlement of the strike was only semisatisfactory for the doctors, who although they do not wish to be civil servants, had hoped to retain the pensions. The formation of a new committee to investigate further the entire setup has been approved by the government and new changes are to be expected in time.

Aviation Medicine

A committee for the study of aviation medicine was recently established in Sweden with Professor G. Kahlson of Lund University as chairman. The committee is to take the initiative in research in aviation medicine, one of its first jobs being to work on the medical problems contributing to flying accidents and safety. Three laboratories have been set up, at the University of Lund, at the Caroline Institute and at the Institute of Physical Culture. "One would think it unnecessary," said Professor Kahlson, "to carry on independent research in Sweden in a subject which has been and is being so thoroughly covered by the British and Americans, not to mention the Russians. Unfortunately, however, the most important results achieved in those countries are still kept secret and we must therefore do our own research and no longer wait for information from other sources."

First Swedish Industrial Disease Clinic

The Swedish Medical Board has proposed the establishment of a badly needed clinic for industrial diseases at Caroline Hospital, which would be the first in Sweden. It is claimed that with all the new industries bringing with them new dangers to health, the time is definitely ripe for a central organization for the investigation of and research into industrial disease occurring throughout the country. A hospital is also planned in conjunction with the experimental body, with beds for about 25 patients.

Poliomyelitis Vaccine

A recent report published by Professors The Svedberg and Arne Tiselius and Dr. S. Gard stated that considerable progress has been made by investigators at Uppsala in the production of a poliomyelitis vaccine. Their experiments with mice have been successful in producing resistance against the disease. The work at Uppsala has been made possible through grants from King Gustav V's 80th Birthday Fund. By the beginning of 1948 it is hoped that King Gustav's Research Institute will be completed in Uppsala at a cost of 1.3 million kronor for the building and 200,000 kronor for the equipment. Various other foundations have contributed to the cost of an electron microscope and other special apparatus.

Influenza Vaccine

A vaccine against influenza is soon to be made in Sweden at the government bacteriological laboratory. Preparatory experiments have already been made and, as soon as a centrifuge ordered from the United States arrives, production is to begin on a large scale. The Swedes are still doubtful about the effectiveness of the vaccine but hope, as soon as more of the preparation becomes available, to determine on the basis of their own research just how satisfactory it is.

Russian Visitors to Stockholm

Several well known Russian physicians arrived in Stockholm recently, and more are to be expected. Professor Egorov, a prominent Soviet brain surgeon, Professor Anatole Frumkin, specialist in renal surgery, and Professor Holdin, cancer scientist, have already arrived. The Russians are guests of Caroline Institute; they will visit and study that institution and also hold lectures on their own experiences in medicine.

Scandinavian Cooperation in Research

Fourteen laboratories in the Scandinavian countries are combining their efforts in an extensive common program to study the thyroid hormones in order to determine the exact effective strength of thyroid gland preparations, according to Dr. Håkan Rydin, chairman of the Nordic committee which recently held a two day meeting in Stockholm. Fourteen pharmaceutical laboratories are working on the same problems and sharing experiences and results, thus saving much duplication of time and effort. The results of their experimentation will be published at the next meeting, scheduled to be held in Norway in the spring.

Death of Ole Chievitz

Professor Ole Chievitz, chief surgeon of the Finsen Institute, died recently at the age of 63. During the German occupation of Denmark he was known as one of the most energetic members of the resistance movement and was twice arrested by the Nazis. He was also of great assistance to Finland and was leader of the Red Cross ambulance unit that went to that country in 1918 and 1939. During the summer of 1941 he worked as a volunteer field surgeon in Finland until the Finnish troops reached the old border.

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D. D. N. J. and foods, F. N. J. The abstracts that follow are given in the briefest possible form (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration]

Abbott Bros. Compound—Pinus Medicine Company, Monticello, Ill. Shipped April 21 and Sept 29, 1941 Composition essentially water, alcohol, sodium salicylate, sodium phosphate, potassium nitrate, extracts of plant materials and flavoring Misbranded because labeling falsely represented product as a treatment for muscular aches and pains in the limbs, sides and back —[*D D. N. J, F D C. 1158, June 1945*]

Anti-Uric.—Anti Uric Company, San Francisco Shipped April 1, 1943. Composition essentially water, alcohol, sugar and small amounts of plant drug extracts. Misbranded because of misrepresentations on label and in accompanying literature that product was an effective eliminant and stimulant diuretic and useful for relieving rheumatic, neuralgic, sciatic, neuritic and muscular pains, upset stomach and some other disorders —[*D. D. N. J., F. D. C. 1138, June 1945*]

Balm.—Oriental Laboratory, St Louis Shipped March 22, 1943 Composition: small amounts of carbolic acid, creosote, camphor and pine tar, in a petrolatum base Misbranded because label failed to warn adequately against unsafe methods of applying this article containing carbolic acid, and falsely represented it as an all purpose ointment for any skin injury or disorder.—[*D. D. N. J., F. D. C. 1156; June 1945*]

Basic Endocrines Nostrums.—Basic Endocrines Sales Company, Inc., Seattle and Salt Lake City. Shipped on various dates in December 1942. In addition to plant and glandular substances, a small amount of dicalcium phosphate was found in No 37 Formula GH-5; matter derived from bile, in No 24 Formula GH-1; thyroid in No 15 Formula GM-15 and No. 3 Formula GM 4 No. 20 Formula GH 4 consisted essentially of animal tissues. Misbranded because of these misrepresentations: That No. 37 was a competent treatment for diabetes mellitus, would increase blood and tissue calcium and relieve pain and nervousness; that No 24 would cure or mitigate liver hypofunction, cirrhosis, cardiac irregularities and some other disorders; that No 15 was efficacious for many ailments, including sexual neurasthenia, premature senility and general debility; that No 3 would help chronic hypo-ovarism and sexual asthenia, among others, and that No 20 was useful in treating many conditions, including acute toxemia, toxic migraine and food allergy.—[*D. D. N. J, F. D. C. 1137, June 1945*]

Buffalo Mineral Water.—Buffalo Mineral Springs Company, Inc, Buffalo Springs, Va. Shipped June 21, 1943. Composition: product reported as a lightly mineralized water. Misbranded because of false representations in accompanying literature that product would improve or restore health and be of great benefit in treating kidney disorders, diabetes, stone or inflammation in the bladder, Bright's disease, alcoholism and many other conditions —[*D. D. N J, F. D. C. 1184; June 1945*]

Corley's Nostrums—Dr. Buren L Corley, trading as Dr. Corley's Products, San Francisco Shipped July 7 and Sept. 12, 1942 Composition: Dr. Corley's Alkaline Broth—essentially plant material, including kelp and celery, with meat extractive and sodium chloride; Dr. Corley's Garlic Tablets—essentially ground vegetables, such as parsley, garlic and onions; Dr. Corley's Laxx—essentially a mixture of karaya gum, whole psyllium seed, anise seed, senna leaf fragments, a small amount of peppermint leaf particles, a trace of buckthorn bark and unidentified seeds, stems and woody material Broth misbranded because falsely represented to be efficacious in alkalizing the blood, neutralizing or combating body acids and treating anemia, asthma, high or low blood pressure, hay fever, rheumatism, and many other disorders Garlic Tablets misbranded because represented as helpful for intestinal inflammation Laxx misbranded because falsely represented to cleanse the intestines thoroughly.—[*D. D. N J., F D. C. 1179, June 1945*]

Fruitola and Traxo.—Pinus Medicine Company, Monticello, Ill Shipped April 21 and Sept. 29, 1941. Fruitola composition: powders (in blue paper): sodium bicarbonate and Rochelle salt; (in white paper): tartaric acid; liquid essentially olive and anise oils Traxo composition: essentially alcohol, water, and extracts of plant materials, including emodin, podophyllin and strychnine Fruitola misbranded because label gave false impression that product would help to clear intestinal tract and regulate flow of bile. Also misbranded because name and label reference to "fruit oils" falsely represented that ingredients were derived from fruits. Traxo misbranded because label falsely represented that article was a tonic and stimulant to the digestive tract and its nerve system; that, when used with Fruitola, it would increase the efficacy of that product, and that label failed to warn against using Traxo, a laxative, when nausea, vomiting, abdominal pains or other symptoms of appendicitis are present —[*D. D. N. J, F. D. C. 1158, June 1945*]

Huzzah, A Vitamin B_1 & B_2 Supplement.—Huzzah Corporation of America, Chicago. Shipped Nov. 20, 1943. Composition: essentially a water solution of glycerin, caramel and phosphoric acid, containing vitamin B_1 and riboflavin. Misbranded because label falsely represented that product would prevent physiologic reactions due to alcoholism, prevent or correct low resistance to alcoholic stimulants, nervousness, exhaustion, headaches, faulty digestion, stunted growth and certain skin disorders, and provide energy and strength —[*D. D. N. J, F. D. C. 1186; June 1945.*] Also misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 6200.*

Hydraphorus with Cinchona.—Leon Chemical Company, Springfield, Mo Shipped Oct 13, 1942 Composition essentially water, with a small amount of phosphoric acid. Label claims as to presence of hydrastis and cinchona misleading, since only traces of these drugs were found. Misbranded for this reason and because label falsely declared that glycerin was an ingredient —[*D. D. N. J., F. D. C. 1141; June 1945.*]

Medrex Ointment and Soap.—William A. Reed Company, Philadelphia Shipped April 7, May 12 and June 30, 1942. Composition Ointment essentially zinc oxide and petrolatum, with small amounts of acetanilid, starch, methyl salicylate, and carbolic, benzoic and salicylic acids; soap contained small amounts of a zinc compound, starch and salicylic acid Misbranded because labeling falsely represented that, when used as directed, both products would be effective for relief of itching and irritation accompanying eczema, and for the treatment of pimples, scalp eruptions, blotches and other skin disorders of external origin —[*D. D. N. J, F. D. C. 1135 and 1230, June 1945*]

Minra.—Stayner Corporation, Berkeley, Calif. Shipped Jan. 30, 1941 Composition: dextrose, about 45 per cent, citric acid, about 28 5 per cent, sodium and potassium bicarbonates, phosphates, salts of iron and calcium, small amounts of manganese and magnesium compounds, and less than 0 001 per cent of copper. Misbranded because mention of calcium lactate on label failed to reveal that the amount of calcium obtained in a directed dose was much less than the normal requirement for this mineral, and because of misleading label representation that recommended dosage supplied sufficient dextrose to relieve fatigue; that use of product would maintain or restore bodily health, make up for calcium deficiency, and (according to circular) would relieve stomach distress, develop muscles, correct impure blood, build strong bones and sound teeth, and do a good many other things —[*D. D. N. J, F. D. C. 1181, June 1945*]

Ourine.—Aurine Company, Inc., Chicago. Shipped between April 6, 1943, and Jan 26, 1944. Product formerly sold as "Aurine." Composition: essentially water, glycerin, boric acid (1.1 per cent), carbolic acid (0.18 per cent) and traces of alcohol, camphor, clove oil and extracts of plant drugs. Misbranded because accompanying booklet, "The Care of the Ears," falsely represented that product, when used as directed, would prevent or remedy deafness, effect good hearing through alleged antiseptic, analgesic, astringent or anesthetic properties; was a safe and appropriate treatment for earaches resulting from bulging or congestion of the tympanic drum; would act as a tonic and relieve local catarrhal conditions, pain, soreness or inflammatory disorders, protect the skin and mucous membranes, overcome ineffective hearing, and had been successfully used by thousands for relief of temporary or partial deafness —[*D. D. N. J., F. D. C. 1136, June 1945.*]

Phenolix Elixir Phenobarbital.—Wayne Pharmacal Supply Company, Fort Wayne, Ind Shipped Nov. 10, 1942. Adulterated because not conforming to standard strength of elixir of phenobarbital. Misbranded because label did not declare quantity or proportion of phenobarbital, a derivative of barbituric acid, a hypnotic substance, or warn that product might be habit forming —[*D. D. N. J., F. D. C. 1163; June 1945*]

Sul-Ray Effervescent Mineral Baths.—Sante Chemical Company, New York. Shipped May 27, 1943 Composition: essentially sulfur, with sodium phosphate, carbonate and borate. Misbranded because labeling falsely represented that product would supply benefits otherwise obtained from a visit to mineral springs and that sulfur in bath water would be effective in treating rheumatism, arthritis, lumbago, gout, sciatica, various skin disorders, muscular aches and itching —[*D. D N. J, F. D. C 1130, June 1945*]

Vbev.—Healthaids, Inc, Jersey City, N J. Shipped July 8, 1941 Composition (claimed on label): diastasic malt syrup, dextrose, whole liquid milk, tricalcium phosphate, ferric pyrophosphate—soluble, molasses, natural vitamin B complex and "Vitamin A and D Concentrate" Government chemists reported that product contained 796 milligrams of calcium per ounce, whereas label falsely gave the figure as 1000 Hence misbranded, and also because of false label claim that product was a new discovery and a new food beverage, developed after years of scientific research and investigation, whereas it was merely a combination of two well known foods. Further misbranded because label falsely represented Vbev as efficacious in the prevention or treatment of a variety of disorders, such as infections, diarrhea, stunted growth and loss of hair, and as providing a valuable supplementary supply of natural B complex, as well as vitamins A and D and the vital minerals calcium, phosphorus, iron and copper —[*D D N J, F. D. C. 1127, June 1945*]

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Dentist's Negligence in Sawing Bridge.—The plaintiff sued for damages for injuries to her face and jaw alleged to have resulted from the negligence of defendant in the removal of a partial denture. From a judgment in favor of the plaintiff the defendant appealed to the Supreme Court of Kansas.

The Supreme Court said that, in the absence of a special contract, a surgeon is not required to exercise extraordinary skill and care but is only required to possess and exercise the degree of skill, care and learning ordinarily possessed and exercised under similar circumstances by members of his profession in the community where the defendant practices, and to use ordinary and reasonable care and his best judgment in the application of his skill to the case.

The plaintiff testified that she consulted the defendant dentist with reference to an extraction. He first thought he could remove a bridge by pulling it off of two teeth but then decided to remove it by using an electric saw. She said he had to "slip the saw, which was round, inside her mouth and had to pull her mouth down to get the saw in." The plaintiff also stated that the defendant did not pad her mouth in any way and put no appliances on her lower lip, but that he did move her lower lip back and her upper lip up. When he started to cut, the saw slipped off and went through her mouth.

The only expert witness called by the plaintiff testified that he had practiced dentistry in Wichita since his graduation from the Kansas City College of Dental Surgery in 1896 and that he had formed an opinion as to what a dentist in that city should give patients with reference to skill, intelligence and learning in treatment. After being shown the bridge which had been removed from plaintiff's mouth, he was asked whether or not, from his years of practice in Wichita, he was familiar with the usual, proper and careful method used by dentists in good standing in April of 1944 for removal of such bridges. On answering that he was, he was asked whether or not the defendant, assuming he attempted to remove the bridge without using any cotton or padding and without using a depressor to hold her lip back and protect it, was acting with the proper, careful and skilful method of removing a similar bridge by dentists of good standing in Wichita. He stated that the defendant was not. On cross examination, however, this expert stated that he did not know whether certain named dentists used metal depressors or not and had never been in the offices of other dentists in Wichita. He further stated that each man has his own method of doing things and that he would not say yes or no on whether use of wooden spatulas for a depressor was an unsafe method, but he added that if the plaintiff had had a Liberty Depressor on her lower lip it would not have been cut.

The defendant argued that in view of the evidence of the plaintiff's expert witness that he had not visited the offices of other dentists in Wichita, which was brought out during cross examination, he could not testify to what they did and therefore there was a lack of expert testimony of the skill and care commonly used by other dentists in like cases in the community. This ignores the direct testimony of the witness as to what he was taught in a reputable dental college and what he had subsequently learned through medical books and periodicals as to the proper methods of treatment and care to be used in similar operations. We conclude, said the Supreme Court, that the trial court did not err in refusing judgment for the defendant at the end of the plaintiff's evidence.

Concerning the defendant's motion for a directed verdict at the close of all the evidence, said the court, we understand that the defendant contends that when he testified as to how he performed the operation and plaintiff failed to rebut this testimony, it left the whole of the evidence in such condition that there was no sufficient, competent evidence to support any verdict in plaintiff's favor. The defendant's description of the operation was, briefly, that while his nurse assistant held back the cheek and lower lip with two wooden depressors and he used another to hold the top, he used the saw with his right hand and cut the bridge. In our opinion, said the Supreme Court, the defendant's contention cannot be sustained. The plaintiff in her case in chief offered proof that in the performance of the operation the defendant had not used depressors of any kind. It was not necessary, after defendant had offered his proof to the contrary, that plaintiff deny his version or again repeat her own.

Accordingly the Supreme Court held that the trial court did not err in any of its rulings and the judgment in favor of the plaintiff was affirmed.—*Harris v. Exon, 170 P. (2d) 827 (Kan., 1946).*

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, Feb. 1, page 347.

BOARDS OF MEDICAL EXAMINERS

ARKANSAS:* *Medical. Examination.* June 5-6. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 5. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Examination.* Los Angeles, March 10-13. Sec., Dr. Frederick N. Scatena, 1020 N. St., Sacramento 14.

CONNECTICUT:* *Medical. Examination.* Hartford, March 11-12. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. *Homeopathic.* Derby, March 11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

GEORGIA: Atlanta and Augusta, June. Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta 3.

INDIANA: *Examination.* Indianapolis, June. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 627 K. of P. Bldg., Indianapolis.

IOWA:* *Examination.* Iowa City, March 17-19. Corresponding Sec., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines 19.

KANSAS: *Examination.* Kansas City, March 25-26. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

MAINE: Portland, March 11-12. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.

MASSACHUSETTS: Boston, March 11-14. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston 33.

MONTANA: Helena, April 1-2. Sec., Dr. O. G. Klein, First National Bank Bldg., Helena.

NEBRASKA:* *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, State Capitol Bldg., Lincoln.

NEVADA: *Examination.* Carson City, May 5. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 13. Sec., Board of Registration in Medicine, Dr. John S. Wheeler, 107 State House, Concord.

NEW JERSEY: Trenton, June 17-18. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, April 7-8. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: *Endorsement.* Winston-Salem, April 30, June 24. *Examination.* Raleigh, June 23-26. Acting Sec., Mrs. L. McNeill, 226 Hillsboro St., Raleigh.

PENNSYLVANIA: Philadelphia and Pittsburgh, July. Acting Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

TEXAS: *Examination.* Galveston, Feb. 20-22. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: March 18, Sec., Mr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

DISTRICT OF COLUMBIA: Washington, April 21-22. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA: May 31. Sec., Dr. M. W. Emmel, University of Florida, Gainesville.

IOWA: Des Moines, April 8. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

OKLAHOMA: Oklahoma City, March 17. Sec., Dr. J. D. Osborn, Jr., Frederick.

OREGON: Portland, March 1. Sec., Board of Higher Education, Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Feb. 12. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

32:545-678 (Nov.) 1946

Rheumatic Fever and Rheumatic Heart Disease in North African and Mediterranean Theater of Operations, United States Army. E. F. Bland.—p. 545.

Notes on Similarity of QRS Complex Configurations in Wolff-Parkinson-White Syndrome. G. E. Burch and J. L. Kimball.—p. 560.

Syndrome of Abdominal Aortic Aneurysm Rupturing into Gastrointestinal Tract: Summary of Literature and Case Report. H. H. Hunt and C. V. Weller.—p. 571.

Auricular Diastolic Murmur with Heart Block in Elderly Patients. D. A. Rytand.—p. 579.

Hypertrophy of Heart of Unknown Etiology in Young Adults: Report of 4 Cases with Autopsies. R. F. Norris and H. H. Pote.—p. 599.

*Parenteral Vitamin B as Agent for Determining Arm to Tongue Circulation Time: Part I. R. E. Swenson.—p. 612.

*Combined Use of Lanatoside C and Quinidine Sulfate in Abolition of Established Auricular Flutter. R. M. Tandowsky, J. M. Oyster and A. Silverglade.—p. 617.

Electrocardiographic Changes Occurring During Treatment with Fuadin Solution. S. B. Beaser and R. Rodriguez-Molina.—p. 634.

Orthostatic Paroxysmal Ventricular Tachycardia. M. Peters and S. L. Penner.—p. 645.

Parenteral Vitamin B for Determination of Circulation Time.—Swenson determined the arm to tongue circulation time by injecting 5 cc. of a solution of vitamin B into the antecubital vein and letting the subject tell when he tasted the substance. In a control group of 50 normal subjects the average time was found to vary from 9.8 to 10.3 seconds for the initial and duplicate determinations respectively. Similar determinations were also made on 52 patients with heart disease. It was found that the circulation time determined by this method parallels the time reported for other test agents. The vitamin B preparation used appears to be nontoxic, has little effect on circulatory dynamics, is readily available, is eliminated rapidly, and has an abrupt end point. The side reactions are minimal.

Lanatoside C and Quinidine Sulfate for Auricular Flutter.—Tandowsky and his associates, using both lanatoside C and quinidine sulfate, observed that, when used in proper sequence, these drugs are valuable for the conversion of established auricular flutter into normal sinus rhythm. Lanatoside C in full digitalizing dosage (1.6 mg.) followed by maintenance dosage (1 to 2 mg. daily) frequently converts auricular flutter to auricular fibrillation and less frequently to sinus rhythm. Following the administration of this drug a slowing of the ventricular rate occurs which is due chiefly to increased auriculoventricular block. This slowing usually precedes the conversion of auricular flutter to auricular fibrillation. Following this conversion by lanatoside C, the use of quinidine has proved of especial value. Maintenance dosage of lanatoside C has proved of value as prophylactic therapy following the restoration of normal sinus rhythm.

American Journal of Clinical Pathology, Baltimore

16:671-736 (Nov.) 1946

Clinical Pathology in the Eighties and Nineties. G. Dock.—p. 671.

Extrinsic Factors Influencing Sedimentation Rate. M. S. Rosen.—p. 681.

Bone Lesions in Early Syphilis: Report of Case. A. M. Lefkovits and K. R. Cross.—p. 693.

Skeletal Lymphosarcomatosis with Secondary Hyperparathyroidism. A. van der Sar and P. H. Hartz.—p. 701.

Clonorchiasis: Report of 2 Cases. E. B. Helwig and R. G. Brown.—p. 714.

Comparison of Methods for Recovery of Eggs of Schistosoma Japonicum from Feces. G. W. Hunter III, J. W. Ingalls and Minna G. Cohen.—p. 721.

American J. Digestive Diseases, Fort Wayne, Ind.

13:341-372 (Nov.) 1946

*Increased Excretion of Glucuronates After Ingestion of Benzoic Acid by Patients with Damaged Liver. I. Snapper, A. Saltzman and E. Greenspan.—p. 341.

Hypertrophic Gastritis Simulating Neoplasm. J. Bank, A. E. Pearce and J. H. Gilmore.—p. 344.

Regional Enteritis and Idiopathic Ulcerative Colitis: Clinical Study. B. J. Weinberg, H. Sorter and H. Necheles.—p. 346.

Clinical Research. H. W. Soper.—p. 350.

Regional Ileitis. Ischiorectal Fistula Preceding and Following Operation for Ileitis: Report of Case. M. Golob.—p. 352.

*Amebiasis: Role of Bacteria in Symptomatology: I. Sigmoidoscopic Findings in Symptomatic and Asymptomatic Cases; II. Effect of Sulfadiazine on Symptoms and Sigmoidoscopic Findings. M. Ellenberg.—p. 356.

Banti's Syndrome Following Prolonged Infectious Hepatitis: Report of 2 Cases. R. L. Fisher and M. Zukerman.—p. 361.

Pathogenesis and Mechanism of Cirrhosis of Liver. A. O. Wilensky.—p. 367.

Glucuronate Excretion Test of Hepatic Function.—Snapper and his associates found that after ingestion of 5 Gm. of benzoic acid by patients with liver cirrhosis or hepatitis the glucuronate reactions are always positive in the second two hour urine specimen, and they are generally also positive in the first and third two hour specimens. This glucuronate excretion is a sensitive liver function test. If after ingestion of 5 Gm. of benzoic acid, none of the three two hour specimens show a positive glucuronate reaction, serious liver damage is not present.

Amebiasis.—Ellenberg reviews observations on 176 unselected cases of proved amebiasis, of which 107 were symptomatic and 69 were asymptomatic. All these patients were subjected to sigmoidoscopy. It was found that the basic pathologic pattern is identical in symptomatic and in asymptomatic cases of Endameba histolytica infection and that the secondary invasion of the amebic ulcerations by bacterial pathogens is a decisive determinant in the symptomatology of amebiasis. More than nine tenths of the cases having amebic lesions with an accompanying inflammatory component showed distinct clearing of the inflammation after the use of sulfadiazine. Specific amebic lesions showed no response to sulfadiazine. The beneficial effects of sulfadiazine were not related to any action on E. histolytica.

*Levels of Blood Pressure in Both Arms and Legs in Normal Subjects and Patients Suffering from Certain Diseases. H. J. Stewart, A. A. Newman and W. F. Evans.—p. 451.

Relative Importance of Certain Variables in Clinical Determination of Blood Pressure. C. E. Kossmann.—p. 464.

*Concentration of Renin in Renal Venous Blood in Patients with Chronic Heart Failure. A. J. Merrill, J. L. Morrison and E. S. Brannon.—p. 468.

*Relief of Pellagrous Glossitis with Synthetic Folic Acid. T. D. Spies.—p. 473.

Results from Subtotal Gastric Resection in Peptic Ulcer: Internist's Viewpoint. T. G. Miller and J. T. L. Nicholson.—p. 476.

Nisulfazole Treatment of Chronic Ulcerative Colitis. R. H. Major.—p. 485.

Role of Hyaluronidase in Human Infertility. R. Kurzrok, S. L. Leonard and Helen Conrad.—p. 491.

Blood Pressure in Arms and Legs.—Stewart and his associates report observations on the blood pressures recorded in all four extremities in 21 healthy persons and 102 patients with various cardiac lesions. The systolic and diastolic blood pressures were higher in the legs than in the arms in normal subjects, in those with hypertension, in patients with rheumatic heart disease with mitral stenosis and mitral insufficiency, in patients with congenital heart disease (exclusive of coarctation of the aorta) and in patients with hyperthyroidism. Higher systolic and diastolic blood pressures were obtained in the arm than in the thigh in 23 cases of coarctation of the aorta, a reversal of the situation encountered in normal subjects and in patients with the diseases mentioned, indicating the diagnostic importance of this finding for coarctation.

Renin in Cardiac Failure.—Merrill and his collaborators obtained renal venous blood from 5 normal subjects and 11 patients with fixed chronic congestive failure. No renin was detected in the renal venous blood or arterial blood of the normal subjects. Significant amounts of renin were found in the renal venous blood of 8 of the 11 patients with chronic heart failure. No renin was detected in the arterial blood. The finding of increased concentration of renin in the renal venous blood of patients with chronic congestive failure affords an interesting explanation for hitherto obscure vasoconstriction phenomena occurring in association with congestive failure.

Folic Acid in Pellagrous Glossitis.—Spies found that folic acid alleviated both macrocytic anemia and glossitis in patients with pellagra, whereas liver extract influenced only the macrocytic anemia, and nicotinic acid ameliorated the glossitis alone.

Cystic Adenomyosis of Uterus. S. Gold and P. J. Kearns.—p. 840.
Solid Teratomas of Ovary with Neurologic Metastases. G. G. Proskauer. —p. 845.

Conservative Surgery in Endometriosis.—Beecham reviews observations in 80 consecutive cases of endometriosis. There seems to be a close relationship between retrodisplacement and endometriosis. The nonpathologic retrodisplaced uterus should be observed at regular intervals for signs of fixation indicating a surgical need for treatment of probable endometriosis. The author has found it possible to salvage ovarian tissue in situ in 23 per cent of women under 45 years of age. Childbearing capacity was salvaged in an additional 52.5 per cent of women under 45 years of age. The author feels that conservative surgery is worth while and should be the major consideration when operating for endometriosis.

Posterior Pituitary Injection in Prolonged Labor.—According to Reid, prolonged labor dependent on uterine inertia and associated with cervical dystocia occurs mostly in primiparous women. Posterior pituitary injection has been administered to 1,609 patients with uterine inertia during labor. With the use of this drug there have been no cases of ruptured uterus or extensive birth canal trauma. The incidence of prolonged labor has been reduced to the low figure of 2 per cent in the clinic patients. The need for midforceps operations was reduced to 0.5 per cent. The need for Dührssens' incisions was small. The author feels that posterior pituitary injection can be administered safely during labor. Its use has decreased the incidence of prolonged labor without deleterious effects on mother or baby.

Pathologic Findings in Genital Bleeding Two or More Years After Cessation of Menstruation.—Of the 514 cases reviewed by Cheek and Davis there were malignant lesions in 36.1 per cent. This is a lower figure than that usually quoted and reflects increasing understanding on the part of the patient of the danger of postmenopausal bleeding, better understanding and cooperation on the part of attending physicians in referring patients for study, and possibly a greater incidence of benign bleeding from endocrine stimulation. Type of bleeding varies from spotting to profuse hemorrhage and has no significance in determining the etiology. Bleeding after the menopause may come from anywhere in the genital tract. To rule out cancer a complete study, including uterine curettage and biopsy of the cervix, is imperative in all cases regardless of the results of pelvic examination.

*Penicillin in Treatment of Gonococcal Infections: Analysis of Results Reported in Literature Through 1945. M. Meads and M. Finland. —p. 586.

Prognosis of Asymptomatic Neurosyphilis.—Hahn and Clark reviewed the records of 1,800 patients who were diagnosed as having asymptomatic neurosyphilis. Two groups of these patients were selected for study as a random sample; the first group was made up of 533 patients with at least two spinal fluid observations and the second group of 467 patients with at least two physical examinations. The observation period was less than two years in approximately 40 per cent and more than five years in approximately 35 per cent of these patients. Race and sex proved to be of slight importance in the prognosis of asymptomatic neurosyphilis. The younger the patient and the more recent the syphilitic infection, the more favorable is the prognosis during the first ten years of observation, but the elapsed time between the acquisition of syphilitic infection and termination of observation has been insufficient in the younger patients for determination of ultimate prognosis. The more strongly positive the initial spinal fluid examination, the less favorable is the prognosis in asymptomatic neurosyphilis. Spinal fluid improvement is a relative but not an absolute guaranty against clinical progression, and spinal fluid progression, in particular, is a grave prognostic sign with respect to the development of clinical neurosyphilis. The prognosis in many patients with asymptomatic neurosyphilis is favorable even when treatment is totally inadequate. Adequate amounts of routine therapy with trivalent arsenical and bismuth compounds are of distinct value in the treatment of many patients with asymptomatic neurosyphilis. No evidence could be found that the addition of tryparsamide was of value in the treatment of asymptomatic neurosyphilis. Fever therapy is the most effective form of treatment in asymptomatic neurosyphilis, as demonstrated by its value in the most resistant patients.

Penicillin in Treatment of Gonococcic Infections.—Meads and Finland present a critical analysis of the results of treatment with penicillin in 21,936 cases of acute gonorrhea collected from the literature to the end of 1945. Gross cure rates of between 92 and 95 per cent were obtained from the initial course of parenteral penicillin given in the most commonly used doses of between 75,000 and 200,000 units, and these rates were not definitely related to the size of the dose within this range. Within the same dose range, however, there were fairly wide variations in cure rates reported by different observers. A dose of less than 75,000 units gave significantly lower cure rates, except perhaps when penicillin X was used. There were also lower cure rates with an initial course of 200,000 units or more, but this was probably related to the choice of cases. Chronicity and the presence of focal purulent complications are probably the most common causes of failure, but the possibility of penicillin-resistant strains and low potency or rapid deterioration of some lots of penicillin was considered.

Clinicians' Responsibility in Teaching of Surgery. A. O. Singleton. —p. 981.

The Anemia of Thermal Burns.—The stubborn and disabling character of the anemia following severe burns has prompted Moore and his associates to determine among other factors how far the customary methods of measuring an anemia suffice for the guidance of therapy and to what extent newer methods of blood volume determinations must be introduced as a clinical routine. Anemia in burned patients has been investigated by serial studies of the red cell mass and bone marrow activity employing a radioactive isotope of iron and by measurements of pigment excretion. True reductions in red cell mass must be distinguished from the false anemia of hemodilution encountered early in the course. Multiple influences including hemolysis, cryptic wound hemorrhage, iron deviation, gastrointestinal absorption, infection and marrow depression enter into the etiology of the anemia. Its anticipation and early replacement is far preferable to late recognition and delayed transfusion. There is no adequate substitute in the clinical care of a severely burned patient for serial objective measurements of the red cell volume.

Peritoneal Irrigation in Acute Renal Failure.—Fine and his associates demonstrate that certain types of acute renal failure need not be fatal if the period necessary for repair can be provided by utilizing an extrarenal pathway as a temporary substitute for the normal excretory function of the kidney. They show that continuous peritoneal irrigation with an appropriate fluid is a satisfactory method of eliminating uremia. It can be used in any case of acute renal failure in which death from uremia is likely and in which recovery of kidney function is considered possible. The control of fluid and electrolyte balance is at least as important as the elimination of nitrogenous waste products and is an integral part of this therapeutic method.

Surgical Treatment of Congenital Pulmonic Stenosis.—The main indication for operation in congenital pulmonic stenosis according to Blalock is evidence of an inadequate flow of blood to the lungs. The absence of visible pulsations in the lung fields, as observed under the fluoroscope, and roentgenographic evidence that the pulmonary artery is small are important in the diagnosis. Whereas the typical case of the "tetralogy of Fallot" is easily diagnosed, there are many borderline cases which are not. If the patient has a hopeless prognosis without an operation, Taussig and the author have taken the position that an exploration is indicated. If doubt still exists after the pulmonary artery is exposed, the pressure in the artery is measured by using a needle and a water manometer. When the pressure is greater than 300 mm. of water an anastomosis is probably inadvisable. Operation has been performed on 110 patients. This figure includes all patients on whom an incision was made and hence some in whom an anastomosis was not performed. A total of 25 patients have died, making a mortality rate of 23 per cent. All the patients with 1 exception who have survived the performance of an anastomosis are improved. A number of the children who could walk only a few feet prior to the operation can now walk a mile or more. Some engage in fairly strenuous exercise.

Penicillin in Established Surgical Infections.—Meleney reviews the results obtained with penicillin in surgical infections under the direction of the Committee on Chemotherapy of the National Research Council. There were 744 cases with sufficiently complete data. Penicillin controls the disease either alone or as an aid to surgery in about two thirds of surgical infections. It is most effective in cases of furuncle, cellulitis, mastoiditis, carbuncle, suppurative arthritis, lung abscess, superficial abscess, brain abscess and osteomyelitis. It is moderately successful in cases of deep abscess, thrombophlebitis, sinusitis, infected soft part wounds, infected operative wounds, otitis media, infected compound fractures and ulcer of the skin. It is not so successful in cases of empyema, infected burns, gas gangrene, actinomycosis, gangrene of the skin, miscellaneous surgical infections, postoperative pneumonia, peritoneal abscess and diffuse peritonitis. It is more successful in the treatment of acute than of chronic infections and if given early rather than late. It is often effective when the sulfonamides have failed. Many localized surgical infections can be successfully treated with local injection of penicillin solution or local application of penicillin in ointment form. "Adequate dosage" may vary from a few thousand to several million units. Penicillin is not as successful in mixed infections as in those caused by a pure culture of a susceptible organism. Clostridium welchi is so often found in a mixed culture with other intestinal organisms that clinical cases of gas gangrene often fail to respond to penicillin. An analysis of the cases in which penicillin had no appreciable effect revealed that in a large proportion of these cases the cultures showed organisms capable of producing penicillinase. Other important causes of failure were resistant strains of staphylococci or streptococci, too little or too late administration of penicillin, associated tuberculosis or diabetes with arteriosclerosis and too conservative surgery. In the septicemia cases the results were better in those due to the hemolytic streptococcus than in those due to the staphylococcus, probably because in the latter type the infection more quickly produces deep metastatic abscesses and vegetation on the heart valves. Four points warrant special emphasis: 1. Penicillin is a valuable adjunct to surgery in surgical infections, and in many instances it can obviate surgery, but it is not a panacea. 2. Local application of penicillin is effective in localized surgical infections if the organisms are susceptible. 3. "Adequate dosage" is the amount which will bring the infection under control and it cannot be determined before the beginning of treatment. 4. A careful and complete bacteriologic analysis is essential to obtain the best results.

Treatment of Benign Menopausal Bleeding. J. R. Willson.—p. 493.
Public Health Aspects of Cancer Control. E. G. Brown.—p. 496.
*Riedel's Lobe of Liver—Report of Case. H. F. Gloyne.—p. 505.

Riedel's Lobe of Liver.—Gloyne defines Riedel's lobe of the liver as a linguiform lobulation or tonguelike prolongation of the anterior margin of the right lobe of the liver. The presence of this lobe has been ascribed to gallstones with enlarged gallbladder, tight lacing in corsets, syphilitic perihepatitis with scarring of the liver and partial or local ptosis of the liver. The condition is rarely seen today. The author observed it in a woman aged 63, confirming the difficulty that may be experienced in preoperative diagnosis. Surgery may be indicated to establish the diagnosis and eliminate the possibility of retroperitoneal cancer or pathologic change of the right kidney or right colon. Cholecystectomy is in order if the gallbladder is diseased and/or pain is a prominent symptom.

Syphilitic Aortitis, with Multiple Fusiform and Saccular Aneurysms of Thoracic Aorta.—p. 730.

Effect of Anticoagulants on Penicillin Therapy in Endocarditis.—Thirty-four consecutive and unselected patients with subacute bacterial endocarditis were treated with penicillin by Priest and his associates. Fifteen received anticoagulants and 19 did not. Anticoagulants failed to prevent major embolism in 5. If the daily dose of penicillin is adequate and treatment is continued long enough, healing of the vegetations will take place as well without as with anticoagulants. The rate of recovery was 100 per cent in the latest 15 consecutive patients, most of whom daily received 1,000,000 units or more. All these patients were treated without anticoagulants. Fatal hemorrhage resulting from the use of anticoagulants was suggested, although not proved, in 2 of them. The additional cost, which is large when heparin is used, as well as the expense and inconvenience to the patient of daily determinations of coagulation or prothrombin time, does not seem justified.

Pantopaque Myelography: Indications and Technic. B. Copleman.—p. 460.

Heartburn in Pregnancy.—According to Roth heartburn is a common complaint in the last trimester of pregnancy. It is due to the regurgitation of gastric contents. Many women experience it only in a recumbent position, and in some the symptoms are severe enough to interfere with sleep. The most effective treatment is the administration of the cholinergic drug neostigmine, the use of thiamine hydrochloride and nicotinic acid, and dietary management. Considering the evident benefit from neostigmine and vitamin B, further trial of these agents is definitely indicated.

Dietary Treatment of Laënnec's Cirrhosis.—Patek says that during a period of nine and a half years 150 patients with cirrhosis of the liver were treated at the Coldwater Memorial Hospital. He reviews observations on the 124 patients who were in the decompensated stage and had either ascites or jaundice. In contrast to the traditional American diet for liver disease, which is high in carbohydrate and low in protein and fat, the present diet is rich in protein and ample in carbohydrate and fat. It consists chiefly of meat, milk, eggs, fruit and green vegetables. Meat is served twice daily, milk five times daily—three times with meals, and twice with 25 Gm. of powdered brewers' yeast. In patients with ascites, fluids are allowed up to 2,000 cc. daily and salt is moderately restricted. Fifty-one of the 124 patients showed signs of clinical improvement, as was indicated by gain in weight, disappearance of ascites, edema and jaundice and changes toward normal values in liver function tests.

*Preparation of Mumps Vaccines and Immunization of Monkeys Against Experimental Mumps Infection. K. Habel.—p. 1655.
Sickness Absenteeism Among Industrial Workers, First Quarter of 1946. W. M. Gafafer.—p. 1664.

Mumps Vaccines.—According to Habel, mumps vaccines have been prepared from infected chick embryo yolk sacs and allantoic fluid. Concentration and clarification of the antigens have been accomplished by ether extraction, by precipitation of urates and by precipitation through *p*H change. Virus has been inactivated by exposure to ether and to ultraviolet radiation. Immunity to mumps in monkeys following immunization with these vaccines was demonstrated by the absence of parotid swelling following test virus inoculation and by the antibody response to vaccine. Vaccine antigen mixed with beeswax in oil as an adjuvant appeared to be superior to saline suspensions in producing immunity.

Penicillin in Vincent's Angina.—Page and Lipman treated 23 patients with Vincent's angina by means of penicillin in the form of pastilles or lozenges without a relapse. The lozenges produced symptomatic relief in from twelve to forty-eight hours. The authors conclude that penicillin in the form of lozenges is well suited to the ambulatory treatment of Vincent's angina.

Pneumonoconiosis in Dock Workers.—Dunner and his associates observed 55 dock workers who for years had been handling cargoes of grains, seeds and certain chemical materials such as bauxite, iron ore, sulfur and manganese. These workers are exposed to large amounts of dust. The analyses of cereal dusts have disclosed the presence of appreciable amounts of silica, fine hairs, starch grains and cellular matter. These substances may produce lung disease. Of 55 grain workers 11 had pneumonoconiosis.

Congenital Patency of Foramen Ovale Cordis, with Sudden Death During Exercise Tolerance Test. C. E. Lumsden.—p. 734.
Cough Syrup. E. M. Boyd.—p. 735.

Pure Penicillin in Ophthalmology.—Sorsby and Ungar point out that until recently supplies of penicillin contained some 80 to 90 per cent of impurities. In contrast, most of the samples now obtainable contain a concentration of penicillin of up to 80 per cent, and limited quantities of pure penicillin are becoming available. Pure penicillin is well tolerated by the eye when applied locally in ointments containing up to 100,000 units per gram or in watery solutions. Intravitreal injection of pure penicillin, though not free from secondary effects, is also well tolerated. Repeated subconjunctival injections of 50,000 units in 0.5 cc. of water are well tolerated. Experimental infections of the anterior chamber are readily controlled by the use of concentrated ointments, subconjunctival injections and systemic administration of penicillin. In vitreous infections subconjunctival injection is the only procedure that was found satisfactory.

Penicillin in Acute Puerperal Mastitis.—Taylor and Way think that adequate control of acute puerperal mastitis can be obtained only by the systemic administration of large doses of penicillin. They administer it by three hourly intramuscular injections of 12,000 to 20,000 Oxford units. Criteria for starting treatment are pyrexia, associated with flushing, and hardening of the breast. The authors report 10 cases. Discomfort was never present for more than three days, and no baby became infected as a result of the continued suckling. There were no recurrences after the cessation of treatment. Owing to the ineffectiveness of sulfonamide therapy in this disease, it should be entirely replaced by penicillin.

Benadryl for Penicillin Urticaria.—Willcox describes the action of benadryl in 6 cases of urticaria, 5 of which were considered to be due to intramuscular penicillin therapy. The doses ranged from 150 to 450 mg. in each case. A reaction was noted in 1 case in which epinephrine was administered concurrently. The results obtained showed success in 5 cases and failure in 1. In 2 of the successful cases there were relapses, in 1 of which further treatment with the drug led to a satisfactory result.

Pulmonary Mycosis. T. G. Brown.—p. 583.

Spread of Infective Hepatitis and Poliomyelitis.—Van Rooyen and Kirk think that both infective hepatitis and poliomyelitis are primarily intestinal maladies. The carrier as well as the immunity rates at the time of an epidemic have never been accurately surveyed for lack of convenient methods. Susceptible individuals who ingest infective hepatitis virus develop the secondary complication of jaundice more frequently than do those who develop secondary paralytic phenomena after ingestion of poliomyelitis virus. The authors interpret the epidemiologic behavior of infective hepatitis in the light of the discovery of the causal virus in human stools. Reference has been made to the spread of infection under conditions in which British troops served in the Middle East Force.

Urea in Treatment of Suppurations of External Auditory Meatus.—According to Williams, urea has been tried in aural furunculosis and has quickly established itself as the treatment of choice in any but the mildest cases. The meatus is first mopped out with wool. Urea is then introduced on a gauze wick, dry for preference. It is sometimes difficult to get much urea to adhere to the dressing by this method alone. An alternative is to use narrow petrolatum gauze, the urea adhering more readily to it and the introduction of the dressing being less disagreeable, since the petrolatum acts as a lubricant. However, the urea is more efficacious in its "drawing" power if used dry, especially if the furuncles have begun to discharge. The dressings are repeated daily, preceded by careful toilet. Once the swelling has subsided and the furuncles have ceased discharging, it is advisable to discontinue the use of urea.

*Fetal Bones in Urinary Bladder: Unusual Termination to Ectopic Pregnancy. H. W. Forshaw.—p. 716.

Psychology of the Tuberculous.—Observations in a sanatorium for tuberculous patients convinced Day that patients who develop pulmonary tuberculosis in the absence of environmental causes often do so because of disease in their psychologic environment—their relation to themselves or to the world outside. In psychologic distress the patient is ready to be ill and the ubiquitous bacilli are there ready to oblige. This is tantamount to saying that tuberculosis provides means for a flight from frustration, for self punishment and all those other dark urges which are continually shipwrecking one's behavior. If such a patient is to recover from his tuberculosis we must treat his concurrent psychologic disease. Retreat in a sanatorium probably brings about changes in many patients, but it is likely that psychiatric aid would expedite their readjustment.

Fetal Bones in Urinary Bladder from Ectopic Pregnancy.—Forshaw reports that a woman from the African bush had passed small bones in the urine on several occasions On the basis of the history and the clinical findings a tentative diagnosis was made of an old ruptured ectopic pregnancy which had ulcerated through into the bladder A suprapubic incision revealed dense adhesions between the uterus and the proximal portion of the left broad ligament and the bladder After the peritoneal cavity was closed the bladder was opened and fetal bones were found The patient made an uneventful recovery

*Gramophone Recordings of Cardiovascular and Respiratory Sounds E H Stokes —p 595
Recording of Cardiovascular and Respiratory Sounds V M Brooker —p 595

Sudeck's Atrophy —Sweetapple says that Sudeck's atrophy usually occurs in the hand or foot It results from minor trauma and leads to pain, joint stiffness, vasomotor changes and bone atrophy out of all proportion to the causative injury The author points out that there is agreement about interrupting either the afferent or the efferent nervous connections with the injured part but that a diversity of opinion exists in the methods of doing it

Lesions of Musculotendinous Cuff of Shoulder.—Gunning stresses the importance of the subacromial structures in relation to painful shoulders, which are often diagnosed as strain muscular rheumatism, neuritis or arthritis In relation to the lesions of the musculotendinous cuff and painful shoulder he discusses bursitis, strain of the musculotendinous cuff, supraspinatus tendinitis or tendinitis of the musculotendinous cuff, partial rupture of the musculotendinous cuff complete rupture of the musculotendinous cuff, calcification in the supraspinatus tendon and frozen or silent shoulder

Recordings of Cardiovascular and Respiratory Sounds —Stokes says that one of the difficulties in the demonstration of auscultatory findings lies in the fact that patients with characteristic signs are frequently not available when required Vascular and respiratory sounds have therefore been recorded on disks, which can be played repeatedly These records are to assist, not to replace, clinical study

New Aspects of Infection in War Surgery Role of Sulfonamides and Penicillin E Curtillet —p 317

Prognosis and Treatment of Great Embolisms of Pulmonary Artery.—The factors on which the diagnosis of embolism is based include, according to Leriche, an operation within the preceding six to ten days, a sudden syncopal attack, anxiety, air hunger, dyspnea cyanosis and a sudden drop in blood pressure The best way to arrive at a localizing diagnosis is by eliminating the sympathetic element by blockage The author and Fontaine resorted to this measure in the form of anesthesia of the stellate ganglion which modifies the picture of embolism and preserves the patient's life The first patient so treated was cured by stellate infiltration, but subsequently stellate anesthesia was effective for only a few minutes patients dying ten minutes later Since infiltration of the stellate not only is of therapeutic value but also serves diagnostic localization Leriche thinks that it ought to be the first measure in the presence of an embolic picture If the condition improves, even if infiltration has to be repeated, embolism involves a secondary branch, but if improvement is very brief the main trunk is obliterated and embolectomy becomes necessary Intravenous injection of procaine hydrochloride can be substituted for stellate infiltration Sixty per cent of the patients with embolism die in less than fifteen minutes Ten minutes is required for the intravenous injection of procaine hydrochloride, and if such an injection has no effect and the patient is unconscious and has no pulse it is useless to operate The immediate mortality of embolectomy has been 70 per cent

Late Results of Splanchnicectomy.—Fontaine and his associates review the late results of 63 splanchnicectomies The operation does not effect a cure in thromboangiitis but in a large number of cases it arrests the disease and, combined with sympathectomy, promotes the collateral circulation Observations on 3 cases of Raynaud s disease in which sympathectomies, splanchnicectomies and adrenalectomies were done disclosed that in this disease further clarification is necessary Dorsal splanchnicectomy provided inferior to Heller s operation in 2 cases of megaesophagus and was even less effective than repeated simple splanchnic infiltrations Splanchnicectomy produced excellent results in megadolichocolon Of 2 cases of habitual vomiting 1 responded to splanchnicectomy and the other did not There was also 1 success and 1 failure after splanchnicectomy for the visceral crisis of tabes Splanchnicectomy was effective in painful hydronephroses

*Should Herniated Disk be Considered Cause or Sequel of, Sciatica? F. Thiébaut.—p. 417.

Sciatica and Herniated Disk.—Thiébaut believes that rheumatic inflammation is the cause of sciatica. Trauma plays an important part in 50 per cent of the cases but is not indispensable. The rheumatic inflammation is responsible for the congestion and the edema of the root, for the thickening of the yellow ligament, for the calcium deposits which infiltrate the periarticular tissues and probably the disk so as to impair its elasticity. The radiculitis is the most important factor causing pain and spasm of the corresponding muscles. This spasm has the tendency to crowd the vertebrae and to compress the disks. The disk may become herniated and impinge on the inflamed root with the result that the interdiscoapophysial space is narrowed. The herniated disk is the sequel and not the cause of the idiopathic sciatica, for which the term rheumatic sciatica seems more appropriate. This concept explains the cure of the sciatica without the removal of the disk and without radectomy and laminectomy in several of the author's cases of sciatica associated with herniated disk.

*Diagnosis of Primary Thrombosis of Internal Carotid Artery in Cervical Region by Means of Determination of Values of Systolic Pressure of Central Artery of Retina. M. Miletti.—p. 655.

Primary Thrombosis of Internal Carotid Artery.—Miletti studied 38 cases of primary thrombosis of the internal carotid artery. Determination of the systolic retinal pressure offers considerable aid in the diagnosis of thrombosis of the internal carotid artery. In failure of circulation in one of the two carotid arteries the retinal systolic pressure is lower on the side of the lesion although the diastolic pressure may be the same on the two sides. Before or after compression of the common carotid artery in the neck there is no difference between the retinal systolic and diastolic pressure on the side of the lesion. Lowering of retinal pressure on both sides results from compression of the normal carotid artery on the side opposite to the lesion, but the drop in retinal pressure is more pronounced on the side of the lesion.

Scurvy and Vertigo. H. Öhnell.—p. 129.
*Roentgenologic and Clinical Aspects of Large Peptic Ulcers. N. H. Krisnapoller.—p. 142.
Treatment of Urticarial Disorders with Vitamin K. P. Kallós.—p. 171.

Scurvy and Vertigo.—The possibility that scurvy may bring on vertigo first occurred to Öhnell in connection with the appearance of the symptoms of Ménière's disease in a patient who had scurvy as the result of a prolonged scorbutic diet. Furthermore, experimental investigations on monkeys disclosed scorbutic changes in the inner ear which, according to generally accepted theories, are of significance with regard to the appearance of vertigo. The author also reviews observations on cases of vertigo in which scorbutic conditions were detected. There were 87 such cases, and in the majority (85 per cent) treatment with vitamin C resulted in improvement in the vertigo.

Roentgenologic and Clinical Aspects of Large Peptic Ulcer.—Krisnapoller found that of a total of 384 patients with gastric ulcer 41 per cent had niches measuring more than 1.5 cm. in the longitudinal axis of the stomach (large niches) and 6.5 per cent had niches measuring more than 3 cm. (giant niches). The frequency of the large and giant niches increases with age. Their favorite site is the body of the stomach, in contrast to the small niches in the pyloric canal. The large ulcers more frequently leave residual niches and more often lead to local recurrences than the small ones. The giant niches show the highest percentages of subacid and achylic curves and in about 50 per cent an increase in the sedimentation rate. The extent of a hemorrhage from the ulcer does not appear to depend on the size of the ulcer. The large ulcers are more often accompanied with skin and cardiovascular diseases than the small ulcers.

Tuberculous Stenosis of Large Bronchi: Clinical, Roentgenologic and Anatomicopathologic Study. P. M. Steiner.—p. 1.
*Treatment of Tracheobronchial Tuberculosis. J. P. Secretan and P. Zuidema.—p. 78.

Treatment of Tracheobronchial Tuberculosis.—Secretan and Zuidema performed bronchoscopies on 98 patients, in 45 of whom tuberculosis of the trachea or the bronchi was demonstrated. Bronchoscopy is indispensable in the diagnosis and prognosis of tracheobronchial tuberculosis, which frequently represents a disease in itself, independent of the specific condition of the lungs. Satisfactory results were obtained with local treatment. The bronchial tree was cleansed and aspirated, and the mucosa cocainized. A 10 to 30 per cent solution of silver nitrate was applied to the lesions of the trachea, while the bronchi were treated with the electrosurgical cautery. In cicatricial stenosis, bronchoscopy with the combined use of a sound and cautery was effective in restoring the lumen and insuring adequate drainage. Perforation of the bronchus occurred only once in the course of 250 bronchoscopies. In contrast to the American point of view, the authors believe that collapse therapy is indicated in tracheobronchial tuberculosis for the control of bronchiectasis. Bronchoscopy does not spread the tuberculous process.

*Complication of Antirabic Vaccine. S. Zabludovich.—p. 1454.

Complication of Antirabic Vaccine.—A butcher was bitten by a pig when killing the animal. Antirabic vaccination was given by false alarm. Seven days after completion of the treatment the patient exhibited bilateral facial paralysis, inability to walk, anuria and acute symptoms simulating acute peritonitis. The successful treatment consisted in daily subcutaneous injections of sodium chloride and dextrose solutions in liberal quantities and daily intravenous injections of vitamin B_1 in doses of 100 mg. The acute symptoms were rapidly controlled. Vitamin B_1 therapy was continued up to a total dosage of 1,500 mg. in two weeks.

Revista Sudamericana de Morfol., Buenos Aires

4:1-992 (May) 1946. **Partial Index**

*Sclerogenic Cardiopathy Due to Avitaminosis B_1. A. E. Bianchi.—p. 1.

Sclerogenic Cardiopathy.—A man aged 37 with a history of avitaminosis B_1 showed symptoms of progressive heart failure, an x-ray shadow of an enlarged heart, acute hypotension and electrocardiographic signs of myocardial damage. Death occurred ten months from onset of the disease. The anatomic diagnosis was cardiac hypertrophy with dilatation, severe myocardial sclerosis and renal infarcts. Lesions were not found in any other organs. Microscopic examination revealed diffuse myocardial sclerosis of nonvascular origin, atrophic lesions of the muscle fibers, intense interstitial edema and mural thrombosis

overlying areas of very thickened endocardium. Bianchi believes these lesions were due to a vitamin B_1 (thiamine) deficiency and proposes the term "sclerogenic cardiopathy from avitaminosis B_1" to designate this entity of heart disease, which is rare.

Direct Electrocardiography in Restoration.—Andreyev and his co-workers carried out electrophysiologic experiments on 100 isolated hearts of children seven to thirty-six hours after the children had died from various infections. The hearts were perfused with a modified oxygenated Tyrode solution. The children were between the ages of several days and 4 years. Direct observation of the revived human heart by electrocardiography proved the presence of multiple foci of excitation in auricular fibrillation. It also established the actual form of activity occurring separately in the left and right ventricles of the human heart. This method should prove valuable in the investigation of many other conflicting problems in electrocardiography.

Sleep in Treatment of Pain.—Kaminski induced a prolonged state of sleep in patients suffering from severe pain that arose after injuries to the peripheral nerves of the upper and lower extremities. A mixture of evipal sodium, barbital sodium and procaine hydrochloride in glucose solution was administered internally in drops. After taking this mixture the patients slept from fifteen to eighteen hours out of every twenty-four. On the third or fourth day of the prolonged sleep the pain became less intense. In moderately severe cases intramuscular injections of evipal and barbital sodium were given into each buttock seven to eight times for one to two days and were combined with intravenous injections of procaine hydrochloride. The intense pain disappeared fourteen to eighteen days later. Relapses have not occurred.

Causalgia and Its Treatment.—Zikeyev induced prolonged sleep of 120 to 168 hours in 37 patients with causalgia following surgery of the nerve. Only 2 patients presented a mild type of causalgia, while the rest showed severe causalgia of long standing. All except 1 recovered. Between doses the patient may awake to a state of drowsiness. Fluids are then administered, and the bladder is emptied. During continued sound sleep, food and fluids are administered by a gastric tube and the bladder is catheterized. The body temperature of the patient is measured at one hour intervals. Pulse and respiration are carefully recorded.

*Reduction of Number of Relapses in Patients with Malaria. C. W. F. Winckel.—p. 1124.

Reduction of Relapses in Malaria.—Winckel says that relapses have been rapid and frequent in regions of the Netherlands in which tertian malaria is endemic. About half of the patients have a relapse (parasitemia and fever) the same year or the year after adequate treatment with quinine. Earlier it had been noted that relapses were much less frequent when patients were treated with quinine and plasmochin than after treatment with quinine alone. When plasmochin was no longer available, recurrences became more frequent. To reduce the high incidence of relapses the author advises treatment with a mixture of quinine sulfate 750 to 900 mg. and pamaquine about 50 mg. daily for two weeks.

Extensive Calcification in Heart at Early Age. F. S. P. van Buchem.—p. 182.

Pressor Substance in Blood of Patients with Renal Hypertension.—Kreutzfeldt employed isolated rabbit ears for various perfusion experiments. Preliminary experiments showed that the vessels of the ear react strongly to weak solutions of epinephrine but that quantitatively the vessels may react differently to the same concentration. The isolated rabbit ear may be considered a sensitive preparation for vasoconstrictive substances, but it cannot be used for quantitative measurement. Plasma and serum from rabbits, calves and man produced vasoconstriction when added to isotonic solution of three chlorides used as a perfusing medium in the isolated rabbit's ear. The degree of constriction proved only approximately proportionate to the concentration. Plasma from normal persons and plasma from patients with renal hypertension both caused vasoconstriction, and the effect of the plasma from patients with renal hypertension was no more pronounced than that of normal plasma. The author's experiments followed Page's method for demonstrating the presence of pressor substance in the blood of patients with renal hypertension except for using defibrinated blood of nephrectomized rabbits instead of dogs as the perfusing medium. The demonstration of the pressor substance in the blood failed, and Page's results were not verified because vasoconstrictive substances were present in both normal blood and that from patients with hypertension.

*Should Herniated Disk be Considered Cause or Sequel of, Sciatica? F. Thiébaut.—p. 417.

Sciatica and Herniated Disk.—Thiébaut believes that rheumatic inflammation is the cause of sciatica. Trauma plays an important part in 50 per cent of the cases but is not indispensable. The rheumatic inflammation is responsible for the congestion and the edema of the root, for the thickening of the yellow ligament, for the calcium deposits which infiltrate the periarticular tissues and probably the disk so as to impair its elasticity. The radiculitis is the most important factor causing pain and spasm of the corresponding muscles. This spasm has the tendency to crowd the vertebrae and to compress the disks. The disk may become herniated and impinge on the inflamed root with the result that the interdiscoapophysial space is narrowed. The herniated disk is the sequel and not the cause of the idiopathic sciatica, for which the term rheumatic sciatica seems more appropriate. This concept explains the cure of the sciatica without the removal of the disk and without radectomy and laminectomy in several of the author's cases of sciatica associated with herniated disk.

*Diagnosis of Primary Thrombosis of Internal Carotid Artery in Cervical Region by Means of Determination of Values of Systolic Pressure of Central Artery of Retina. M. Miletti.—p. 655.

Primary Thrombosis of Internal Carotid Artery.—Miletti studied 38 cases of primary thrombosis of the internal carotid artery. Determination of the systolic retinal pressure offers considerable aid in the diagnosis of thrombosis of the internal carotid artery. In failure of circulation in one of the two carotid arteries the retinal systolic pressure is lower on the side of the lesion although the diastolic pressure may be the same on the two sides. Before or after compression of the common carotid artery in the neck there is no difference between the retinal systolic and diastolic pressure on the side of the lesion. Lowering of retinal pressure on both sides results from compression of the normal carotid artery on the side opposite to the lesion, but the drop in retinal pressure is more pronounced on the side of the lesion.

Scurvy and Vertigo. H. Öhnell.—p. 129.

*Roentgenologic and Clinical Aspects of Large Peptic Ulcers. N. H. Krisnapoller.—p. 142.

Treatment of Urticarial Disorders with Vitamin K. P. Kallós.—p. 171.

Scurvy and Vertigo.—The possibility that scurvy may bring on vertigo first occurred to Öhnell in connection with the appearance of the symptoms of Ménière's disease in a patient who had scurvy as the result of a prolonged scorbutic diet. Furthermore, experimental investigations on monkeys disclosed scorbutic changes in the inner ear which, according to generally accepted theories, are of significance with regard to the appearance of vertigo. The author also reviews observations on cases of vertigo in which scorbutic conditions were detected. There were 87 such cases, and in the majority (85 per cent) treatment with vitamin C resulted in improvement in the vertigo.

Roentgenologic and Clinical Aspects of Large Peptic Ulcer.—Krisnapoller found that of a total of 384 patients with gastric ulcer 41 per cent had niches measuring more than 1.5 cm. in the longitudinal axis of the stomach (large niches) and 6.5 per cent had niches measuring more than 3 cm. (giant niches). The frequency of the large and giant niches increases with age. Their favorite site is the body of the stomach, in contrast to the small niches in the pyloric canal. The large ulcers more frequently leave residual niches and more often lead to local recurrences than the small ones. The giant niches show the highest percentages of subacid and achylic curves and in about 50 per cent an increase in the sedimentation rate. The extent of a hemorrhage from the ulcer does not appear to depend on the size of the ulcer. The large ulcers are more often accompanied with skin and cardiovascular diseases than the small ulcers.

Tuberculous Stenosis of Large Bronchi: Clinical, Roentgenologic and Anatomicopathologic Study. P. M. Steiner.—p. 1.

*Treatment of Tracheobronchial Tuberculosis. J. P. Secretan and P. Zuidema.—p. 78.

Treatment of Tracheobronchial Tuberculosis.—Secretan and Zuidema performed bronchoscopies on 98 patients, in 45 of whom tuberculosis of the trachea or the bronchi was demonstrated. Bronchoscopy is indispensable in the diagnosis and prognosis of tracheobronchial tuberculosis, which frequently represents a disease in itself, independent of the specific condition of the lungs. Satisfactory results were obtained with local treatment. The bronchial tree was cleansed and aspirated, and the mucosa cocainized. A 10 to 30 per cent solution of silver nitrate was applied to the lesions of the trachea, while the bronchi were treated with the electrosurgical cautery. In cicatricial stenosis, bronchoscopy with the combined use of a sound and cautery was effective in restoring the lumen and insuring adequate drainage. Perforation of the bronchus occurred only once in the course of 250 bronchoscopies. In contrast to the American point of view, the authors believe that collapse therapy is indicated in tracheobronchial tuberculosis for the control of bronchiectasis. Bronchoscopy does not spread the tuberculous process.

*Sclerogenic Cardiopathy Due to Avitaminosis B_1. A. E. Bianchi.—p. 1.

Sclerogenic Cardiopathy.—A man aged 37 with a history of avitaminosis B_1 showed symptoms of progressive heart failure, an x-ray shadow of an enlarged heart, acute hypotension and electrocardiographic signs of myocardial damage. Death occurred ten months from onset of the disease. The anatomic diagnosis was cardiac hypertrophy with dilatation, severe myocardial sclerosis and renal infarcts. Lesions were not found in any other organs. Microscopic examination revealed diffuse myocardial sclerosis of nonvascular origin, atrophic lesions of the muscle fibers, intense interstitial edema and mural thrombosis

overlying areas of very thickened endocardium. Bianchi believes these lesions were due to a vitamin B_1 (thiamine) deficiency and proposes the term "sclerogenic cardiopathy from avitaminosis B_1" to designate this entity of heart disease, which is rare.

Temporary Elimination of Phrenic Nerve in Hemoptysis.—Stangl performed phrenemphraxis in 125 cases of hemoptysis associated with pulmonary tuberculosis. Temporary elimination of the phrenic nerve is suggested for all cases in which usual treatment is ineffective and in which more extensive surgical intervention must be omitted for danger of death resulting from very poor general condition. Phrenemphraxis may also prevent the complications often associated with phrenic avulsion.

Direct Electrocardiography in Restoration.—Andreyev and his co-workers carried out electrophysiologic experiments on 100 isolated hearts of children seven to thirty-six hours after the children had died from various infections. The hearts were perfused with a modified oxygenated Tyrode solution. The children were between the ages of several days and 4 years. Direct observation of the revived human heart by electrocardiography proved the presence of multiple foci of excitation in auricular fibrillation. It also established the actual form of activity occurring separately in the left and right ventricles of the human heart. This method should prove valuable in the investigation of many other conflicting problems in electrocardiography.

Sleep in Treatment of Pain.—Kaminski induced a prolonged state of sleep in patients suffering from severe pain that arose after injuries to the peripheral nerves of the upper and lower extremities. A mixture of evipal sodium, barbital sodium and procaine hydrochloride in glucose solution was administered internally in drops. After taking this mixture the patients slept from fifteen to eighteen hours out of every twenty-four. On the third or fourth day of the prolonged sleep the pain became less intense. In moderately severe cases intramuscular injections of evipal and barbital sodium were given into each buttock seven to eight times for one to two days and were combined with intravenous injections of procaine hydrochloride. The intense pain disappeared fourteen to eighteen days later. Relapses have not occurred.

Causalgia and Its Treatment.—Zikeyev induced prolonged sleep of 120 to 168 hours in 37 patients with causalgia following surgery of the nerve. Only 2 patients presented a mild type of causalgia, while the rest showed severe causalgia of long standing. All except 1 recovered. Between doses the patient may awake to a state of drowsiness. Fluids are then administered, and the bladder is emptied. During continued sound sleep, food and fluids are administered by a gastric tube and the bladder is catheterized. The body temperature of the patient is measured at one hour intervals. Pulse and respiration are carefully recorded.

*Reduction of Number of Relapses in Patients with Malaria. C. W. F. Winckel.—p. 1124.

Reduction of Relapses in Malaria.—Winckel says that relapses have been rapid and frequent in regions of the Netherlands in which tertian malaria is endemic. About half of the patients have a relapse (parasitemia and fever) the same year or the year after adequate treatment with quinine. Earlier it had been noted that relapses were much less frequent when patients were treated with quinine and plasmochin than after treatment with quinine alone. When plasmochin was no longer available, recurrences became more frequent. To reduce the high incidence of relapses the author advises treatment with a mixture of quinine sulfate 750 to 900 mg. and pamaquine about 50 mg. daily for two weeks.

Extensive Calcification in Heart at Early Age. F. S. P. van Buchem. —p. 182.

Pressor Substance in Blood of Patients with Renal Hypertension.—Kreutzfeldt employed isolated rabbit ears for various perfusion experiments. Preliminary experiments showed that the vessels of the ear react strongly to weak solutions of epinephrine but that quantitatively the vessels may react differently to the same concentration. The isolated rabbit ear may be considered a sensitive preparation for vasoconstrictive substances, but it cannot be used for quantitative measurement. Plasma and serum from rabbits, calves and man produced vasoconstriction when added to isotonic solution of three chlorides used as a perfusing medium in the isolated rabbit's ear. The degree of constriction proved only approximately proportionate to the concentration. Plasma from normal persons and plasma from patients with renal hypertension both caused vasoconstriction, and the effect of the plasma from patients with renal hypertension was no more pronounced than that of normal plasma. The author's experiments followed Page's method for demonstrating the presence of pressor substance in the blood of patients with renal hypertension except for using defibrinated blood of nephrectomized rabbits instead of dogs as the perfusing medium. The demonstration of the pressor substance in the blood failed, and Page's results were not verified because vasoconstrictive substances were present in both normal blood and that from patients with hypertension.

Book Notices

Atlas of Genitourinary Pathology. Prepared at the Army Institute of Pathology, Washington, D. C. from Material in the Registries of the American Urological Association by Nathan B. Friedman, Major, M. C., A. U. S., and J. E. Ash, Col., M. C., A. U. S. Cloth. Pp. 215, with illustrations. Washington, D. C., 1946.

This atlas follows the form of previous ones prepared at the Army Institute of Pathology for specialists. As the title implies, it does not represent a textbook but rather a pictorial panorama of the morbid processes in genitourinary diseases. The material which comprises this study includes that made available from the Tumor Registry of the American Urological Association as well as the immense amount of material which is available to the Institute from the Army. In such a compilation as an atlas it is impossible to present smooth, flowing accounts of disease processes such as would be possible in a monograph. The authors have attempted to show "that the morbid anatomy of the genito-urinary tract (is) a live and stimulating subject, which well repays study." They have succeeded in this endeavor.

There are several statements to which exception might be taken, however. On page 20 the authors state that 25 per cent of all women have "auxiliary glandular structures outside the muscular wall of the urethra which form the so-called female prostate." It would be exceedingly difficult to distinguish the glands in the accompanying photomicrograph from periurethral glands of Albarran. In the section on cysts of the kidney, mention is not made of peripelvic cysts. There is an excellent summary concerning the condition which has variously been called "crush" kidney or "transfusion" kidney. On page 76 a clear distinction is not made between squamous metaplasia of the epithelium of the renal pelvis and leukoplakia. Many urologists would not agree to the classification of testicular tumors, in which a division is made between seminoma of the testis and embryonal carcinoma of the testis. Most pathologists have regarded these two terms synonymous. Indeed, from the photomicrographs, it would seem that the authors are describing what has been generally regarded as a monocellular type of teratoma under the term embryonal carcinoma. The accompanying photographs are generally good. The photomicrographs utilizing higher magnification are excellent. Those with lower magnification are mediocre, and, in general, the gross photographs could be improved. The discussions and clinical data which accompany the illustrations are too abbreviated and fragmentary to be of much value. The atlas, however, serves as an excellent guide to the study of pathology of the genitourinary tract and contains much of practical value for any one interested in lesions of this region.

The Chest: A Handbook of Roentgen Diagnosis. By Leo G. Rigler, M.D., Professor and Chief, Department of Radiology, University of Minnesota, Minneapolis. Cloth. Price, $6.50. Pp. 352, with illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1946.

This treatise is a compact, well organized review of the roentgen diagnosis of diseases of the chest. The format is arranged for easy reading, and the descriptions are clear and concise without excess verbiage.

It is introduced by a pertinent section which orients the reader as to the importance and value of roentgenologic studies of the chest and indicates the attendant difficulties of the interpretation. A description of the methods of examination used in roentgenography and roentgenoscopy is included in this handbook together with a review of the special devices (body section roentgenography, photofluorography) and methods (bronchography) utilized in roentgen ray examination of the chest. There is included in this book not only diseases of the lung but of the mediastinum, the pleura and the chest wall. A particularly useful section is that devoted to the normal roentgen findings of the chest and their variations.

The reproductions of the roentgenograms are excellent, and the arrangement is such that easy reference to the descriptions in the text is possible. The cases presented are authoritative and convincing, since nearly all the conditions which are described are those in established, proved cases.

The book is particularly useful to physicians other than radiologists who have need for ready reference to the roentgenologic observations and changes in diseases of the chest and to a discussion of the differential diagnoses. It also serves as an excellent review for radiologists because of its complete survey of the various pathologic entities likely to be encountered in the roentgen ray examination of the chest.

Although this book is an exceedingly useful reference, it was not intended and should not be considered as a source book or compendium of all the available information in the roentgenologic aspects of diseases of the chest.

This is one of the best books in the handbook series on roentgen diagnosis.

Lehrbuch der Physiologie in 33 Vorlesungen. Von Emil Abderhalden, Professor an der Universität Zürich. Tenth-Twelfth edition. Cloth. Price, 34 Swiss francs. Pp. 480, with 235 illustrations. Benno Schwabe & Co., Klosterberg 27, Basel 10, 1946.

One of the reviewer's favorite criticisms of text books of physiology is that each author applies his own conception of the sequence and proportion of subject matter. Out of the total of 458 pages in this book, secretion and alimentary function occupy 41 pages, blood 32, circulation and respiration 79, kidney 13, sensorium and special senses 165, motorium 18 and neurophysiology 107. This suggests a serious imbalance as well as an illogical interrelation of functions. This is regrettable in a text enjoying the prestige which this one does. From a practical point of view there are many subjects so sketchily treated that one can scarcely find any concrete factual information. The illustrations are well integrated, and many of them appear to be original. There is no specialized treatment of the physiology of nutrition, endocrines, reproduction or growth. The long list of references to original work is almost valueless because of the incompleteness of the references. The book is of value because of the author's own analysis of scientific data but is certainly not to be recommended very highly as a text for student use.

A Textbook of Clinical Neurology. By J. M. Nielsen, B.S., M.D., F.A.C.P., Associate Clinical Professor of Medicine (Neurology), University of Southern California, Los Angeles. Second edition. Cloth. Price, $7.50. Pp. 699, with 190 illustrations. Paul B. Hoeber, Inc., 49 East 33rd St., New York 16, 1946.

This is the second edition of a good textbook in neurology for medical students. It has been revised and contains many more entities with full descriptions than did the first edition. The book is valuable primarily because the material in it is presented in relation to anatomic localization. This is one of the most practical and easily understood methods of a teaching textbook in neurology. The illustrations are excellent. Aphasia, apraxia and agnosia receive excellent discussions. The author speaks of a dietetic management in the epilepsies with restriction of water intake. There has been considerable controlled research in regard to diet and water intake, and no relationship or correlation was found in regard to epilepsy. There are other controversial points in the text, but they are minor and do not in any way detract from the value of this book to medical students. It is highly recommended.

Psychiatry Today and Tomorrow. By Samuel Zachary Orgel, M.D., F.A.P.A., Attending Psychiatrist, Hillside Hospital, Bellerose, L. I. Cloth. Price, $6. Pp. 514. International Universities Press, 227 W. 13th St., New York, 1946

This is a new work which reflects the throes of transition which psychiatry is currently suffering as it evolves from its mystical and classificatory phases into a truly scientific medical specialty.

On the one hand Orgel clings to the outmoded Kraepelinian systems of stratifying "mental diseases"; on the other, he strives for a dynamic understanding and presentation of the aims, adaptations and vicissitudes of human behavior. In the latter respect his translation of orthodox psychoanalytic mythology into meaningful etiologic concepts is often apt, although in his attempts to achieve simplicity and clarity Orgel's exposition occasionally becomes sophomoric. Thus on page 51 he says "Freud has used [the Oedipus complex] to describe a normal situation occurring in every one's life, which the Oedipus myth describes so graphically, emphasizing the abnormal solution with the resultant penalty. As you look back upon this newborn 'omnipotent' child you will find that his complete dependence on his mother must persist for a long time if he is not to perish. He is jealous of [his siblings] because of their demands upon mother and wishes them out of the way, which is identical to dead. The boy hates [his father] as a rival when father acts the part of rightful owner of mother, when he takes mother away, goes out with her, treats her as his property, and insists on sleeping with her. The child turns away from mother and tries to satisfy his need for love on himself—he becomes autoerotic."

The intent of such passages is clear: the deviated patterns of behavior are not in themselves disease entities nor the expression of mystical "complexes"; instead, all behavior, normal and "abnormal," is the resultant of an interplay of endowment, experience and individual adaptation.

While Orgel does not explicitly expand this modern dynamic approach to psychiatry, his survey of the field is sufficiently broad to encompass some of its applications to criminology, social work and the cultural problems of mental hygiene. The book is recommended to medical students and practitioners.

Les yeux et la vision des vertébrés. Par A. Rochon-Duvigneaud. Paper. Pp. 719, with 500 illustrations. Masson et Cie, 120 Boulevard Saint-Germain, Paris 6^{e}, 1943

This book is an extensive description of comparative anatomy, histology, physiology and embryology of the eye. Starting with a thorough study of the human eye, the author passes in review the visual organ throughout the manifold classes of the Vertebrates, stressing the specific data for every group, in the structure of the eyeball and the visual function.

Of the immense amount of material in this textbook a few hints of the facts and conclusions are as follows: The ocular tension is very low in the group of the fishes, but is comparable to that of the human eye for all the aerial vertebrates. The canal of Schlemm, missing in the series of the fishes, exists in all aerial vertebrates.

The pupillary reaction, exclusively reflex and unilateral in the groups of the fishes, crocodiles, lizards, snakes and birds, starts definitely to be consensual in the eye of the cat and the dog, although here the reaction of the nonilluminated eye is always weaker. The consensual reaction is 100 per cent—that means equal for the illuminated and the nonilluminated eye—only in the group of the Primates.

As a matter of fact the division in inferior and superior vertebrates is genuine also, as far as the visual apparatus is concerned. The inferior Vertebrates, up to and including the birds, present visual and motor independence of the eyeballs. Only the mammals have conjugated eyes and the foveal binocular vision exists in the eyes of the apes and man. This statement is mainly based on anatomic observations (total chiasm and crossed chiasmal fibers). Naturally, functional testing of the apes appears uncertain.

The volume, well printed, well organized and exquisitely illustrated, is of great value to the ophthalmologist who is interested in the field of comparative anatomy and physiology of the eye; it is undoubtedly a vital addition to any study of zoology. Published in the war period, it is all the more remarkable that this excellent work of a distinguished ophthalmologist and an authoritative zoologist could appear at all under such difficult circumstances.

The Treatment of Bronchial Asthma. By Vincent J. Derbes, M.D., Instructor in Medicine and in Preventive Medicine, Tulane University of Louisiana School of Medicine, New Orleans, and Hugo Tristram Engelhardt, M.D., F.A.C.P., Instructor in Clinical Medicine, Baylor University College of Medicine, Houston, Texas. With Chapters by a Panel of Contributors. Cloth. Price, $8. Pp. 466, with 61 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London W. C. 2; 2083 Guy St., Montreal, 1946.

This treatise on bronchial asthma owes its general excellence to the authoritative points of view of its many contributors. In twenty-three chapters all important aspects of this widespread disease are carefully covered, including the discussion of its predisposing, contributing and exciting factors, and its pathology, immunology, symptomatology and treatment. Worthy of special mention are the chapters on the role of foods by F. W. Wittich, on differential diagnosis by W. W. Sodeman and on nonallergic treatment by J. S. La Due. A comprehensive statistical survey was provided by L. I. Dublin and J. H. Marks. A broad physiologic point of view is maintained throughout, and a few inconsistencies in emphasis from chapter to chapter merely reflect the individual stands of the contributors. The chapter on parasitic agents in the causation of asthma wanders rather far afield from its title. The detailed descriptions and numerous illustrations of surgical treatments does not leave the reader with the impression that these are, as yet, in a strictly investigative stage. One may question whether the inclusion of a complete chapter, however excellent, on cardiac asthma might not confuse the uninitiated in regard to the relationship of this disease to bronchial asthma.

On page 164 errors in conversion of decimals to fractions occur, while on page 174 and following pages the ragweeds are accorded the status of a botanic family, contrary to current opinion. Although the iontophoretic test is dismissed in less than one sentence, an illustration is devoted to it (page 149). Many allergists will question the advisability of employing the strongest extract first when "titrating" individual sensitivity (page 359) for fear of untoward reactions; the feasibility of maintaining coseasonal pollen treatment at intervals as long as five to seven days, and the relative tolerance of most pollen-sensitive patients for maximum single doses of 20,000 pollen units (page 361 and following). No mention of the new antihistaminic agents or of aerosol penicillin is found.

These are, however, only minor criticisms. Undoubtedly, the book will prove a valuable source of information and guidance to those faced with the problems of the management of this troublesome disease.

Allergy in Practice. By Samuel M. Feinberg, M.D., Associate Professor of Medicine and Chief of the Division of Allergy, Northwestern University Medical School, Chicago. With the collaboration of Oren C. Durham, Chief Botanist, Abbott Laboratories, North Chicago, Illinois, and Carl A. Dragstedt, Ph.D., M.D., Professor and Chairman of the Department of Pharmacology, Northwestern University Medical School, Chicago. Second edition Cloth. Price, $10.50. Pp. 838, with 35 illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1946.

This is a second edition of a book which first appeared in 1944. It contains many additions which help to make the book one of the best published on the subject of allergy. The book consists of thirty chapters dealing with all phases of anaphylaxis and allergy, These chapters cover completely all clinical and theoretic considerations and include an up to date bibliography on each subject.

This revised edition contains a chapter on pollens and pollen allergy. This constitutes the most complete and thorough treatment of the subject of pollens in connection with allergy. It includes an up to date account of the pollen surveys in the entire world, and newer methods of pollen counting and pollen standards are published for the first time in a book.

A valuable contribution is the chapter which covers all conditions of allied allergy, such as rheumatic fever, periarteritis nodosa, acute disseminated lupus erythematosus, Löffler's syndrome and tropical eosinophilia. These are discussed competently and in detail, and their relation to allergy is clearly brought out.

A chapter on the role of histamine in anaphylaxis and allergy by Dr. Carl A. Dragstedt offers a concise account of the subject by one who has been an outstanding experimenter and authority in that field.

This book also contains a chapter which deals with newer drugs which can be grouped as histamine antagonists (benadryl and pyribenzamine). This should be of extreme clinical interest to all those who are called on to use these drugs for the treatment of allergic disorders.

The chapter on mold allergy is extensive. It is based on a rather wide personal experience which the author has had in this field.

As was stated before, this book is probably one of the finest available books on the subject of allergy.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

EXERCISES FOR PALATE AFTER BULBAR POLIOMYELITIS

To the Editor:—In recent years there has been considerable progress in retraining of muscles after anterior poliomyelitis has left residual paralysis. However, the work done seems to be confined to extremities that have lost function. Has any rehabilitation work been done with patients who have had bulbar poliomyelitis with cranial nerve involvement? A young woman with history, physical signs and laboratory findings of bulbar poliomyelitis is now convalescent, with slight difficulty in swallowing, nasal twang in speech and deviation of the uvula to the left. Neurologic examination is otherwise negative. At the height of illness there was regurgitation through the nose and severe slurring of speech. Completely normal function of the palate may possibly return in three months, but meanwhile are there any voice or speech exercises the patient may do in hope of augmenting or speeding the restoration of function?

M.D., Iowa.

Answer.—It is correct to assume that most patients with bulbar involvement recover completely, particularly as regards swallowing and speech. Facial nerve involvement is more likely to persist, although the prognosis is good. Certainly, exercises are helpful. The exercises for the soft palate should direct particular attention to the side away from which the uvula is deviated. Like other muscle training following poliomyelitis it should be started before a faulty pattern becomes habitual and should be practiced regularly, preferably more than once a day. Certain representative exercises might be listed:

1. Yawn to the point of feeling a stretch as the soft palate is elevated. The patient should look into a mirror and make an effort to arch the lower side of the soft palate and pull the uvula over toward the center, the tongue being held down.

2. If this is not successful, the sagging region may be stimulated gently with a tongue depressor.

3. Make the sound *a* while looking in the mirror and keeping the soft palate elevated (the *a* sound is nasal when the soft palate sags).

4. Protrude the tongue slightly and curl it up at the end, then retract it strongly, making pressure along the alveolar ridge as it is drawn back. This tends to stimulate the swallowing reflex.

Weakness of the muscles of the lower jaw and failure to masticate the food properly may contribute to the difficulty in swallowing. Chewing motions and lateral movements of the jaw will then be helpful. If lack of breath pressure reduces the volume of tone, breathing exercises should be practiced with emphasis on blowing out.

If the facial muscles also are involved, the weakened movements may be practiced before a mirror, gentle assistance being given by the patient's own finger in moving the lips or cheek to the position corresponding to that on the other side of the face. Laughing and crying make the pull toward the stronger side more noticeable.

Additional exercises for the pronunciation of certain letters and sounds may be found in "The Rehabilitation of Speech" by West, Kennedy and Carr, published by Harper & Brothers.

CAUSE AND TREATMENT OF VERTIGO

To the Editor:—What is the physiologic basis of vertigo? A patient has had vertigo for two months following a minor head injury and a mild cerebral concussion. Please discuss treatment.

H. B. Taylor, M.D., Berea, Ky.

Answer.—True vertigo with a definite sense of rotation is always due to pathologic change in the vestibular mechanism of the peripheral ear or in the central pathways of the vestibular nerve in the pons or cerebellum. Dizziness consisting of lightheadedness or faintness, without a definite systematized sense of rotation, is generaly due to disturbed cerebral circulation and occurs in hypertension, hypotension, arteriosclerosis, anemia, reflex vagal slowing of the heart and many other conditions.

Dizziness following head injury or concussion is generally of the vascular type rather than a true vestibular vertigo. Histamine in extremely dilute doses sometimes hastens recovery from the prolonged symptoms following concussion. The histamine solution should be given subcutaneously in 1:100,000,000 dilution, 0.1 cc. every four days. If there is no improvement after three or four injections it should be discontinued. If there is improvement it may be continued as required.

OSTEOGENESIS IMPERFECTA

To the Editor:—A boy aged 2 years has had nine spontaneous fractures since the age of 6 weeks. Usually the long bones have been involved, and the fractures unite promptly without excess callus formation. All blood studies have been negative, the most recent showing phosphorus 2.8 mg. and calcium 11 mg. per hundred cubic centimeters and the blood Wassermann reaction negative. The father of the child is unknown; the mother is free of syphilis and has had no other children. The child is rather large for his age and well nourished. He has been given a properly balanced diet including a good quantity of milk and cod liver oil. X-rays have not revealed any abnormalities, except that at the time of the first fracture there was some softening of the skull, which promptly cleared up following an increase in dosage of cod liver oil. I do not think that this is a case of Albers-Schönberg disease (marble bone disease) because of the normal blood findings and the fact that the fractures heal without excess callus formation. Please discuss the diagnosis and treatment.

M.D., Maryland.

Answer.—From the description in the query, a diagnosis of fragilitas ossium or osteogenesis imperfecta is suggested. Mention is not made of the China blue sclera, broad skull, rather pinched features and triangular face which are seen in those cases. The description given in the query does not suggest marble bone. The phosphorus is slightly low, but the calcium is normal. Endocrine therapy such as thyroid, parathyroid and thymus has been unsuccessful in these cases. Beyond good general care and food, fresh air and other hygiene measures there is not much one can do. In fragilitas ossium or osteogenesis imperfecta there is a tendency for fractures to be easily sustained up to the age of puberty. After puberty the tendency is for the bones to become more solid and for fewer fractures to occur.

FOUNDER AND GOUT

To the Editor:—In a recent article in the *Saturday Evening Post* the statement was made that founder, a disease of horses, bears a resemblance to human gout. Although uric acid gout affects birds, and guanine gout pigs, I have not seen references to gout in horses. If the author's statement is correct and there is a resemblance to human gout, in what does this similarity consist besides the locus affected? Do horses with founder have hyperuricemia, tophi, acute articular attacks and radiologic changes? Is the disease limited to a particular group of horses, for example, thoroughbreds?

M.D., Illinois.

Answer.—Gout does not affect horses, and founder in horses does not resemble human gout except that it affects the foot or feet of horses and commonly follows overeating.

Founder, or laminitis, is a disease of the fleshy laminas of the horse's feet, producing severe pain and fever. It does not affect a special breed of horses or feet of any special construction. The cause of the disease is a matter of speculation. The most common cause is believed to be heavy overfeeding, chiefly of grains (barley, wheat or corn) and also of green plants. Other supposed causes are metritis in recently foaled mares, long-continued work or excess work on hard pavements.

IMMUNIZATIONS FOR KENYA COLONY

To the Editor:—A patient expects to visit Kenya Colony, British East Africa, on a big game hunting expedition. What diseases are prevalent in this area? What immunizations are advised? Where can this immunizing material be obtained?

Donald G. Mershon, M.D., Chicago.

Answer.—The infectious diseases now prevalent in Kenya are smallpox, typhoid, louse borne relapsing fever, amebic and bacillary dysentery, cerebrospinal meningitis and malaria. Plague and tick typhus occur sporadically. On the basis that yellow fever is present, though rare in man, Kenya has been officially declared to be within the yellow fever endemic area by UNRRA under international sanitary conventions. The person going to Kenya should definitely be immunized against smallpox, yellow fever and typhoid. The decision regarding tetanus immunization depends as elsewhere on the risk of accident and should be left to the judgment of the physician. In the Chicago area, vaccination against yellow fever is performed at the outpatient clinic of the U. S. Public Health Service, 4141 Clarendon Avenue, Chicago, at times determined in advance by telephone. The other vaccines are available through commercial channels.

RIBOFLAVIN ALLERGY

To the Editor:—A white woman aged 50 complained of symptoms typical of ocular riboflavin deficiency and had a dietary history which confirmed this tentative diagnosis. The patient stated that she was not able to drink milk. Five mg. of riboflavin by mouth daily was prescribed. However, her family physician said the patient was allergic to riboflavin. What is the incidence of allergy to riboflavin?

M.D., Ohio.

Answer.—Reports of allergic reactions to riboflavin have not been found.

RENAL GLYCOSURIA

To the Editor:—A patient wishes to marry a girl who gives a history of renal diabetes. During a routine examination this girl was found to have 3 to 4 per cent sugar in the urine and a normal glucose value in the serum. A glucose tolerance test was normal, the values rising to 145 mg. per hundred cubic centimeters and reaching 80 mg. per hundred cubic centimeters again after one and one half hours. The renal threshold for glucose was about 130 mg. per hundred cubic centimeters. A kidney function test was normal. What is the life expectancy of renal diabetic patients and what is the prognosis? Frank Matthias, M.D., New York.

ANSWER.—Renal glycosuria is a benign condition in which, because of a renal threshold for sugar lower than the average normal, glucose appears in the urine at levels of blood sugar lower than 160 to 180 mg. per hundred cubic centimeters. It has no relation to diabetes mellitus, although certain patients with diabetes may have a renal threshold lower than the average normal just as individuals without diabetes do. Although over a period of years there has been some controversy in the literature, the general consensus now is that the prognosis is excellent and that the patient with renal glycosuria has a normal life expectancy.

This statement takes for granted that the diagnosis of renal glycosuria has been made with care. Care must be taken to exclude patients with borderline glucose tolerance curves who might be classified more accurately as having "potential diabetes." To avoid pitfalls such as this, certain physicians have insisted that, before the diagnosis of renal glycosuria is made, an arbitrarily chosen period of three years must elapse during which the patient is kept under observation. Furthermore, some workers make the diagnosis of renal glycosuria only in those persons in whom the renal threshold for sugar is lowered and in whom sugar appears in the urine even in the fasting state, i. e., in the presence of a blood sugar of about 100 mg. per hundred cubic centimeters or below.

It is obvious that if a large enough group of persons with renal glycosuria is followed over a sufficient number of years, a certain small percentage will develop diabetes just as one would find in any similar group of people selected at random. This however cannot be taken to indicate that renal glycosuria bears any relation to diabetes or is apt to progress to diabetes.

EFFECT OF PAPER DUST

To the Editor:—Pulmonary x-ray studies of a man aged 50 demonstrate typical pneumonoconiosis with severe and extensive bilateral fibrosis and nodular masses in the left hilus. The patient worked in the paper industry for twelve years, where he was exposed to large concentrations of paper dust engendered in cutting paper. What is the nature of paper dust and what is its effect on the lungs? George C. Coe, M.D., Chicago.

ANSWER.—If the x-ray pattern is characteristic of a pneumonoconiosis and other disease can be ruled out, it is essential to make certain that there was no previous employment that might involve exposure to dust. If this can be established, it would then be necessary to investigate the atmospheric environment in the paper cutting operation. It seems improbable that this procedure would produce fragments of paper small enough to be inhaled. However, the paper might be coated with sizing, pigments or other substances that could produce inhalable dust. One should also investigate any other operations in the vicinity of the paper cutting operation that could give rise to atmospheric contamination. An analysis of settled dust or air floating dust from the vicinity of the patient's last job is advised to establish particle size, as well as physical, chemical and mineralogical characteristics.

INTERNAL CONTROL KNEE PROSTHESES

To the Editor:—A middle aged rather heavy set woman has had an amputation of the left leg 2 inches above the knee joint. She cannot use her artificial leg satisfactorily although she has had it for two years. She walks awkwardly with a cane. Since she is a school teacher, more freedom of movement is desired. Is this amount of stump too long for inside controls? M.D., Oklahoma.

ANSWER.—If the amputation described in the query is approximately 2 inches from the distal articular surface of the femur, it is through the cancellous flare of the bone. A good stump of this length is frequently fitted with a partial end-bearing prosthesis that carries part of the body weight on the end of the stump, the remainder being distributed up the thigh and on the pelvis. A stump such as described is usually too long to permit the use of a full size mechanical knee.

The value to the patient of the internal control knees now available is questionable. The most important factor is to have the knee joint hinges properly placed, and to have adjustable friction in the joints or knee mechanism.

A great deal of research in the development of better artificial limbs is being carried out in several locations under the supervision of the Committee on Prosthetic Devices of the National Research Council. Improvements are being developed for all types of prostheses, but they will not be commercially available until they have been tried thoroughly and released for production.

The success of an artificial limb depends to a large extent on the physical agility and mental attitude of the patient. A good reference is the recent publication Amputation Prosthesis, by Atha Thomas and Chester C. Haddan (Philadelphia, London and Montreal, J. B. Lippincott Company, 1946).

ADMINISTRATION OF PENICILLIN AFTER PENICILLIN SENSITIZATION

To the Editor:—If a true serum reaction occurs a few days after the last injection of a course of penicillin, is it safe to give penicillin again later if necessary? M.D., Kansas.

ANSWER.—It is possible to give penicillin a second time to patients who have become sensitized to it, provided it is done with care. A small trial dose should be used to determine whether or not the patient is still sensitive. In some instances the sensitivity to penicillin will decrease over a period of six months to a year so that a second course may be given without reaction. In other instances penicillin may be used a much shorter time after the first reaction without difficulty. In any event, once a patient has become sensitized to penicillin it is always well to test with a small single injection before starting a second course.

NONOPERATIVE TREATMENT OF FISTULA IN ANO

To the Editor:—Please discuss the nonoperative treatment of fistula in ano (nontuberculous). The use of penicillin in sodium morrhuate has been described to treat pilonidal cysts (*New York State J. Med.* **46**:891, [April 15] 1946). Has this technic been used to treat fistula in ano? M.D., New York.

ANSWER.—In fistula in ano there is a break in the lining of the bowel. When a patient has diarrhea or a forceful constipated movement, there is likely to be contamination with stool, with a consequent reinfection of the tract. The lining of a chronically inflamed tract is firm scar tissue, and it is common knowledge that healing often occurs for long periods only to break down after an episode of diarrhea or constipation. No doubt treatment with penicillin might cause such a remission, but the mechanical fixation of the bowel to the tract predisposes to another tear. Surgical treatment offers a good chance of permanent cure, whereas a lightly healed scar is a constant threat of more trouble.

SULFONAMIDE SENSITIVITY

To the Editor:—What is the proper method to desensitize a registered nurse who is allergic to sulfonamide drugs even to the point of caring for patients under sulfonamide treatment? Milton P. Graham, M.D., Aberdeen, Wash.

ANSWER.—It is assumed that the nurse is sensitive to more than one sulfonamide. The degree of sensitivity manifested is most unusual. It would be important to know what the manifestations of hypersensitivity are before recommending any method of desensitization. Methods of desensitization include the oral administration of small doses of a sulfonamide and then increasing the doses gradually. Another method involves the subcutaneous injection of minute doses of a sulfonamide initially and then increasing the doses carefully. Any approach to this problem is time consuming and not without danger. Sensitivity to sulfonamides may endure for years.

CARCINOGENS

To the Editor:—What dose of 20-methylcholanthrene is used to produce skin cancer in mice, rats and rabbits? Where can 20-methylcholanthrene be purchased? Manuel D. Navarro, M.D., Manila, Philippines.

ANSWER.—There are many doses and methods of applying 20-methylcholanthrene to produce cancer in mice, rats and rabbits. An excellent review of the problem is given in "Survey of Compounds Which Have Been Tested for Carcinogenic Activity" by J. L. Hartwell, 1941. This is a publication of the National Cancer Institute, Bethesda, Md.

Any of the large drug companies either will be able to provide methylcholanthrene or can direct the applicant to a satisfactory source of this material.

ENDOMETRIOSIS AND PREGNANCY

To the Editor:—A secundipara, aged 27 is now three months pregnant and has, in addition to her pregnancy, several polypoid masses of tissue which are growing into the vagina from the left posterior surface of the cervix. Five months ago a similar tumor was removed from that area and subjected to microscopic examination. This was reported as showing "fairly numerous alveoli surrounded by a loose cellular stroma which resembles islands of endometrium, although the picture is not typical. Diagnosis, extensive chronic cervicitis, possible endometriosis (not definite)." Because the patient was anxious to have a child if possible, radical treatment was not instituted at that time. With the advent of this pregnancy the apparent endometriosis has been growing luxuriantly, and bleeding occurs on the lightest sponging. There is no evidence of any infiltration in the rectovaginal septum. I have been unable to find any information regarding the course of endometriosis under the influence of pregnancy. Moreover, the textbooks state that these patients are usually sterile. I wonder whether to treat this patient conservatively, to attempt to remove the vaginal tumors by cautery or the application of radium, whether to contemplate a vaginal delivery or, because of a likelihood of a serious hemorrhage when the cervix begins to efface and dilate, perform an elective cesarean section. Theoretically, if a cesarean section is performed the ovaries should be removed in order to inactivate the ectopic endometrium. Any suggestions based on the experiences of others with endometriosis during pregnancy would be appreciated.

T. A. Strang, M.D., Long Beach, Calif.

Answer.—It is true that at least 50 per cent of women who are operated on for endometriosis have never had a baby. It appears incongruous to consider the likelihood of a pregnancy in the presence of endometriosis, yet there have been reports of pregnancies associated with endometriosis. The pregnancy may take place in the presence of either internal endometriosis (adenomyosis or adenomyoma) or external endometriosis. In most of the 12 reported cases of internal endometriosis the indication for operation was considered to be a fibromyomatous uterus. In 5 cases there was a rupture of the uterus, and endometriosis was found at the site of the rupture. There was atony of the uterus and postpartum hemorrhage in 3 cases. An adenomyoma caused dystocia during labor in 2 cases, necessitating delivery by cesarean section.

The most common sites of external endometriosis complicating gestation are the rectovaginal septum and the ovarian regions. There are reports of 11 cases of the former type and 7 of the latter. In the rectovaginal type the symptoms usually resembled those of threatened or inevitable abortion. The correct diagnosis was made by specular examination together with biopsy confirmation. This type of endometriosis usually increased up to the fourth month of pregnancy and then retrogressed in size until term.

There are reports of 2 cases of cervical endometriosis. For a description of these cases as well as a complete review of the subject of endometriosis associated with pregnancy and an extensive bibliography see Scott, R. B.: Endometriosis and Pregnancy, with a Report of 2 Cases, *Am. J. Obst. & Gynec.* **47**:608 (May) 1944.

In a case like that cited it is best to pursue a conservative policy during pregnancy. If bleeding is troublesome, the polypoid masses should be destroyed with the electric cautery. If this case follows the pattern of most of the reported cases of rectovaginal endometriosis, the masses will regress in size after the fourth month. Radium should not be used both because it is unnecessary and because it may do harm to the fetus. Since there may be endometriosis in the pelvic cavity, because of the danger of rupture of the uterus, postpartum hemorrhage and dystocia it may be advisable to perform an elective cesarean section on the patient near term. After delivery of the baby the ovaries, broad ligaments and cul-de-sac should be carefully inspected. If endometriosis is present, as much of it as possible should be removed; but one ovary or at least a part of an ovary should be left in situ. This should be done on nearly all young women even though a second operation or x-ray castration may have to be carried out later. In some cases in which an ovary cannot be left in situ it is advisable to implant thin pieces of healthy ovarian tissue in the omentum or in the abdominal wall.

PIGMENTATION AFTER BURNS

To the Editor:—A patient received a first degree burn of the lower part of the leg from boiling water that splashed through a nylon stocking. There is now a discolored area at the site of the burn which appears to be permanent and similar to a tattoo. Have other cases been reported?

G. C. Scanlan, M.D., De Witt, Iowa.

Answer.—Burns frequently result in temporary pigmentation of the skin. Such discoloration lasts longer on the lower extremities and sometimes remains permanently. This pigmentation is due to melanin and not necessarily materials deposited in the skin from without. Ammoniated mercury ointment in a concentration of 1 to 3 per cent used cautiously over a prolonged interval may be useful for removing some of the pigment.

PERSISTENT VAGINAL DISCHARGE IN CHILD

To the Editor:—A girl aged 5 years has a history of a possible insertion of a foreign body into the vagina about June 15, 1945. Since that time she has had periodic exacerbations of mucoid and mucoserous discharge with evidence of external vaginitis. Numerous cultures have shown the presence of nonhemolytic Staphylococcus aureus and Escherichia coli. X-ray studies have been negative on two occasions. Examination under anesthesia showed absence of a foreign body. Therapy has consisted of penicillin solution, penicillin ointment and Aci—fel (to change the ph of the vaginal mucosa). The treatment was successful each time, but each time after the treatment was stopped there was a recurrence. Escherichia coli was at first thought to be a contaminant but is now considered to be pathogenic. Please discuss further diagnostic measures and treatment.

M.D., New York.

Answer.—The x-ray studies and examination under anesthesia almost certainly have ruled out the presence of a foreign body. However, it is conceivable that a small, soft, foreign body, such as a wad of cotton, may still be present. If a rectal examination was not made while the child was under the anesthetic it should be done now, and if the vagina was not inspected through a urethroscope or similar instrument this too should be done.

In the majority of instances vaginal discharges in infants and young children disappear spontaneously even without treatment. This statement is true of gonorrheal vulvovaginitis as well as of nongonorrheal infections. This child has had considerable treatment. It would be wise now to stop all treatment except the use of ordinary soap and water cleansing of the external genitals and perhaps a bland ointment. If there is any itching, an antipruritic may be included in the ointment.

TINNITUS AURIUM

To the Editor:—Are there any recent developments in the treatment of the annoying symptom of tinnitus aurium associated with mild perceptive deafness especially common in patients past middle age?

M.D., Iowa.

Answer.—The exact mechanism of tinnitus is unknown except that it is frequently associated with impaired hearing. In some cases of otosclerosis, tinnitus has improved or been relieved by the fenestration operation. There was no other known treatment for tinnitus until the recent suggestion that the sympathetic plexus on the median wall of the promontory be removed for this symptom. The operation of tympanosympathectomy has proved successful in a few cases of unbearably severe unilateral tinnitus. In other cases the operation has been unsuccessful. The exact indications and results are not yet known. The original article by Julius Lempert describing this procedure appeared in the *Archives of Otolaryngology* **43**:199 (March) 1946.

EFFECT OF BROWN FAT EXTRACTS ON METABOLISM

To the Editor:—In the Queries and Minor Notes section of The Journal, Jan. 27, 1945 the statement appeared that extracts of the "brown fatty tissue" of the interscapular region produced a drop in metabolism of 20 to 30 per cent when injected into rats. What is the source of this information?

M.D., Ontario.

Answer.—The statement concerning the effect of the "brown fatty tissue" on metabolism was based on a note by C. F. Wendt (Ueber Wirkungen eines extraktes aus dem braunen Fettgewebe des winterschlafenden Igels: IV. *Ztschr. f. physiol. Chem.* **249**: 182IV, 1937). It should be added that the lowering of the basal metabolic rates in rats was accompanied with a state of depression, and almost anything that causes a state of depression will do that. For further references see chapter XXXI of Sleep and Wakefulness, by Nathaniel Kleitman (University of Chicago Press, 1939).

CIRCUMCISION OF THE NEWBORN

To the Editor:—The reply to the query on "Circumcision of Newborn" in The Journal, Nov. 9, 1946, does justice to the advisability of doing such a procedure. However, the statement that hemorrhage in the newborn should not be feared unless the baby is suffering from some blood dyscrasia is not correct. On page 102 in the eleventh edition of Holt and McIntosh, the authors state, "it is now clear that a latent hemorrhagic tendency is present in all newborn infants and that hemorrhages will develop in the presence of minimal trauma." Thus every newborn infant should be regarded as having a temporary bleeding tendency. Such a tendency, which is associated with an actual deficiency of prothrombin as well as a possible disruption in the conversion of prothrombin to thrombin, is prevented either by the administration of vitamin K to the mother a few hours before delivery or by the direct administration of vitamin K parenterally to the child after delivery. This hemorrhagic state usually ceases by the fifth to the seventh day, probably as the result of the intestinal production of vitamin K by bacterial action. Therefore it is advisable to perform circumcisions at the end of the first week or later rather than at the time of delivery. If this operation should be undertaken at the earlier time, vitamin K should be administered prophylactically and readministered in case of oozing from the operative site.

CLINICAL SIGNS OF DIAGNOSTIC IMPORTANCE IN CONJUNCTIVITIS

PHILLIPS THYGESON, M.D.
San Jose, Calif.

There has been increasing recognition of the importance of a causal diagnosis in conjunctivitis in recent years, due no doubt to the fact that specific chemotherapy has been made available for a number of important types of the disease. In addition to its value as a guide to therapy, causal determination is important for prognosis, since it is obviously often of great value to be able to predict accurately the clinical course and outcome of a conjunctival infection.

In routine office practice facilities for bacteriologic and pathologic examination are frequently not available, and advantage must therefore be taken of such causal indications as can be obtained from careful gross and slit lamp examination of the conjunctiva and the contiguous structures. It is not generally recognized that reliable differentiation of many of the major types of conjunctivitis can be made on clinical examination alone, independently of laboratory observations. The following report discusses these clinical observations and their diagnostic significance.

THE DIAGNOSTIC VALUE OF PREAURICULAR ADENOPATHY

Enlargement of the preauricular lymph nodes which drain the conjunctiva is almost unknown in catarrhal or purulent conjunctivitis of bacterial origin, although transient swelling of the nodes is occasionally seen in severe hordeola, particularly the internal variety. Enlargement of the nodes is, however, a characteristic of certain special types of conjunctival disease, especially of those caused by viruses and fungi.

Three types of adenopathy are seen. In the first type there is a palpable, nontender or only slightly tender enlargement of the nodes, not grossly visible. This type is characteristic of acute follicular conjunctivitis, particularly acute follicular conjunctivitis Béal,[1] and of inclusion conjunctivitis. In rare instances it is seen in acute trachoma but never in chronic or low grade trachoma. The second type is a visible but not grossly prominent adenopathy in which the nodes are tender to palpation and in which the sublingual and submaxillary nodes are sometimes involved. This type of change is characteristic of epidemic keratoconjunctivitis[2] and of the rare cases of acute herpetic conjunctivitis. The third type of nodular change is a grossly visible adenopathy which constitutes a prominent feature of the disease and produces gross disfigurement; suppuration of the nodes in this type is not infrequent. It is this type of adenopathy which is characteristic of the oculoglandular syndrome of Parinaud which includes such various conjunctivitides as leptotrichosis conjunctivae, tuberculosis of the conjunctiva, lymphogranuloma venereum conjunctivitis, syphilis of the conjunctiva, oculoglandular tularemia, etc.

Preauricular adenopathy is only rarely seen in any other types of conjunctivitis except, of course, as it may occur as part of a general enlargement of the lymph nodes. Palpation of the preauricular nodes should therefore be a routine part of the examination of any conjunctival disease of unknown causation.

THE DIAGNOSTIC VALUE OF CHANGES IN THE LID MARGINS

Blepharitis[3] is often the source of chronic conjunctivitis and neglect of examination of the lid margins may result in failure to recognize and treat the primary focus of a conjunctivitis resistant to all local conjunctival therapy. The blepharitis may occasionally be so mild as to be overlooked in gross examination, but in this event examination with the slit lamp readily reveals the abnormal condition of the margin. The cause of the conjunctivitis is often indicated by the appearance of the blepharitis. Diplobacillary infection, for example, is typically angular and spares the meibomian glands and follicles of the cilia, whereas the staphylococcic variety has a considerable tendency to involve these structures; the occurrence of ulcers at the bases of the cilia may in fact be considered pathognomonic of staphylococcic infection.

Seborrheic dermatitis of the eyelids, when uncomplicated with secondary infection, is recognized by the heavy, soft, greasy scales which are far different from the hard, dry, tenacious crusts of staphylococcic blepharitis. When seborrheic dermatitis is suspected it is always well to examine the scalp, since a severe infection of the scalp usually precedes the infection of the lid margins.

Meibomitis, with or without blepharitis, is also often the source of a chronic conjunctivitis, and digital expression of the meibomian glands and observation of the expressed material should be a part of the routine examination of the conjunctiva in conjunctivitis. The abnormality of the secretion is recognized by its copious amount and by its color and consistency. The normal meibomian secretion is a thin transparent oil.

Read before the Section on Ophthalmology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 4, 1946.

Many ophthalmologists forget that the common wart[4] and the nodule of molluscum contagiosum,[5] when they occur on the margin of the lid, usually produce chronic conjunctivitis and keratitis. A molluscum nodule, particularly when on the lower lid, may be inconspicuous and readily overlooked.

Residual swelling from recurrent styes indicates a residual staphylococcic infection of the lid margins which may well be the source of a chronic conjunctivitis.

Chronic edema of the eyelids due to blockage of lymph vessels is a characteristic feature of lymphogranuloma venereum keratoconjunctivitis[6] and can be considered almost pathognomonic of the infection.

Abnormalities of the Puncta and the Canaliculi.—Swelling, redness and dilatation of one or both lacrimal puncta is characteristic of Streptothrix concretions, which constitute an important cause of unilateral conjunctivitis. The diagnosis can be made by expression of cheesy concretion material from the punctum by pressure along the canaliculus. Microscopic examination of this material always shows Streptothrix elements.

CONJUNCTIVAL CHANGES OF DIAGNOSTIC IMPORTANCE

Minor Changes.—All types of infectious conjunctivitis are characterized by the brilliant red color of the conjunctiva due to hyperemia and formation of new vessels. Allergic inflammations, on the other hand, have a characteristically milky appearance. This is often striking, particularly in vernal catarrh, and is useful for diagnosis. It is probably due to the predominance of edema over cellular infiltration in allergic inflammations.

Small subconjunctival hemorrhages involving the bulbar conjunctiva suggest influenza bacilli or Koch-Weeks conjunctivitis, but their diagnostic value is by no means clearcut, as they may also occur, although much more rarely, in other types of bacterial infection, notably pneumococcic infections.

Bulbar chemosis should immediately suggest gonococcic conjunctivitis, of which it is often an early sign, occurring even before the appearance of gross cellular infiltration and exudation. It may occur rarely, however, in other severe conjunctival infections, and its value as an early sign in trichinosis should never be overlooked. In this condition there is no inflammation of the conjunctiva proper.

The character of the conjunctival secretion is of some diagnostic value. The secretion from allergic conjunctivitis, particularly vernal catarrh, has a high fibrin content and is stringy in character in contrast to the flaky or amorphous exudate of an ordinary bacterial infection. A foamy, whitish secretion collecting at both inner and outer angles always suggests conjunctivitis due to, or associated with, an overactivity of the meibomian glands. A scanty secretion in the presence of an acute conjunctival inflammation is always suggestive of a virus infection.

Papillary Hypertrophy.—The microscopic type of papillary hypertrophy, which gives the velvety appearance to many types of acute and chronic conjunctivitis, carries no diagnostic significance. The gross variety, on the other hand, which is often known as giant papillary hypertrophy and of which the palpebral hypertrophy in vernal catarrh is the outstanding example, is of great diagnostic value. Its occurrence on the upper tarsal conjunctiva, most prominently near the upper border, is almost diagnostic of vernal catarrh. Otherwise it is seen extremely rarely and only in chronic infections of great severity such as chronic gonococcic conjunctivitis. I saw this condition a number of times in Egypt and Tunisia but never have seen it in this country. This type of papillary hypertrophy has sometimes been confused with follicular hypertrophy, but when doubt occurs, examination with the slit lamp permits easy differentiation, since the follicle has an avascular center whereas the papilla has a central vascular core.

Follicular Hypertrophy.—The conjunctiva has a normal adenoid layer, and an occasional lymphoid follicle may be seen in the conjunctiva of young persons, particularly in the fornices. Follicles are never seen on the normal tarsal conjunctiva, however. The diagnostic value of the follicle depends primarily on its location and secondarily on its consistency and relative prominence. Thus, follicles involving the upper tarsal conjunctiva are always suggestive of trachoma, whereas follicles which spare the upper tarsal conjunctiva but involve the fornices and the lower fornix predominantly always suggest folliculosis or follicular conjunctivitis. The follicles of trachoma are soft, gelatinous and easily expressed, while the follicles of folliculosis and follicular conjunctivitis are hard and expressible only with the greatest difficulty. There is no essential difference between the follicles of folliculosis and of follicular conjunctivitis, but in the latter they are much less prominent, since they may be partially or completely buried in the coexisting subepithelial infiltration.

Granulomatous Changes.—Apart from the small granulomas which may result from buried foreign bodies or ruptured chalazia, conjunctival granulomas are generally associated with oculoglandular conjunctivitis, of which conjunctival tuberculosis and oculoglandular tularemia are the outstanding examples. Both of these diseases have granulomatous conjunctival nodules which may ulcerate. In tularemia the nodules are usually rather numerous and are accompanied by considerable inflammatory reaction, in most instances severer than that found in tuberculosis. In leptotrichosis conjunctivae the occurrence of small, whitish or grayish necrotic foci[7] without gross ulceration is a characteristic and almost pathognomonic feature. These foci must be distinguished from conjunctival concretions which may have been present prior to the onset of the particular inflammation.

Single large granulomas without diffuse conjunctival inflammation should be considered as suggestive of rhinosporidiosis[8] and should be subjected to microscopic examination. This disease, though admittedly rare, has been reported from several parts of the country.

Conjunctival Ulcers.—As mentioned above, conjunctival ulceration is characteristic of conjunctival tuberculosis and oculoglandular tularemia but it may also be seen rarely in other conditions, such as chancre of the conjunctiva and acute pemphigus. The ulcers of acute pemphigus are readily distinguished from other ulcers by their shallow character and transient nature.

Formation of Membrane and Pseudomembrane.—For the purposes of this discussion, the term pseudomembrane refers to fibrin coagulum located on the epithelium but readily removable without damage to it. In a true membrane, on the other hand, coagulation of the fibrinous exudate has also occurred in the epithelium and in the subepithelial tissues so that removal of the membrane leaves a bleeding, rough surface. Conjunctival pseudomembranes are of two types, the fine, transient type and the thick, relatively permanent type. The outstanding example of the first type is the extremely fine, transparent membrane which is characteristic of vernal catarrh in the active phase and indeed almost pathognomonic of the disease. Fine, transient pseudomembranes, generally less transparent than those seen in vernal catarrh, may occur occasionally in hyperacute conjunctivitis of several types, including gonococcic conjunctivitis and even epidemic keratoconjunctivitis.

Thick, opaque, more lasting pseudomembranes immediately suggest diphtheria of the conjunctiva, and treatment with diphtheria antitoxin may be begun on the basis of their appearance alone. Similar thick pseudomembranes do occur, however, in beta hemolytic streptococcic infections of the conjunctiva and particularly in the endogenous variety, in which they may persist over a period of many years. It should be recognized, moreover, that they sometimes occur in erythema multiforme and occasionally in ocular pemphigus. Examination of the nose and throat should never be neglected, therefore, when conjunctival membranes or pseudomembranes are present, since the finding of stomatitis points to the diagnosis of erythema multiforme or pemphigus, whereas nasal or nasopharyngeal membranes indicate diphtheria or beta hemolytic streptococcic infection. It should also be remembered that formation of pseudomembrane or membrane may follow extensive radiation of the eye.

Cicatrization.—Conjunctival scars are of great diagnostic value. Omitting for the purposes of this discussion the scars which follow injury, operation for chalazia or burns, only three diseases need be considered in differential diagnosis; namely, trachoma, pemphigus and diphtheria. The scars of trachoma involve the upper tarsal conjunctiva predominantly and those of ocular pemphigus the lower tarsal conjunctiva and fornix predominantly. In ocular pemphigus there may be obliteration of the entire lower fornix. This never occurs in trachoma, and shrinkage of the lower fornix is always less than that of the upper. It should be remembered that, although trachoma sometimes heals with mild scarring, there is always sufficient cicatrization to be recognized in careful examination with the slit lamp.

The scarring of diphtheria is generally diffuse, and there is usually not much shrinkage of the fornices.

It should also be remembered that radiation often causes formation of scars and that, since application of radium is a common procedure in vernal catarrh, radium scars are not uncommonly seen.

The Phlyctenule.—The conjunctival phlyctenule is pathognomonic of phlyctenular conjunctivitis and is believed to be an allergic reaction to a bacterial antigen, most commonly tuberculoprotein. When typical the phlyctenule cannot be confused with any other structure, but occasionally differentiation must be made from the limbal excrescences of vernal catarrh, from localized episcleritis and from inflammation involving the pinguecula. Inflammation involving this latter structure is by no means uncommon and probably forms one special type of episcleritis. Unlike conjunctival phlyctenules, corneal phlyctenules lack diagnostic value. They are difficult to distinguish from catarrhal infiltrates, and diagnosis must in fact be based on the simultaneous occurrence of conjunctival phlyctenules.

Conjunctival Concretions.—Concretions in the conjunctiva as distinguished from infarcts of the meibomian glands always indicate the occurrence of past or present chronic conjunctivitis. Their diagnostic value is slight, but when they occur in large numbers they can be considered suggestive of old trachoma.

Bitôt's Spots.[9]—These areas of keratinization are typically triangular in shape and lie at the temporal limbus with the base to the limbus. As seen on examination with the slit lamp, they have a characteristic appearance, exhibiting folds concentric with the limbus and dry, greasy, opaque surfaces. They usually indicate a vitamin A deficiency, although in tropical countries their occurrence has been reported in the absence of such deficiency.[10] Bitôt's spots may occur elsewhere than at the limbus, but the first lesion of vitamin A deficiency is almost always in this location. They are generally bilateral but occasionally affect only one side. There is almost always an associated disturbance of the corneal epithelium which gives it a punctate opacification readily recognized on examination with the slit lamp. Although not grossly visible, this opacification is sufficient to dull the normal corneal luster.

LIMBAL AND CORNEAL LESIONS OF DIAGNOSTIC IMPORTANCE

Limbal Follicles.—Limbal follicles involving the upper limbal region predominantly must be considered pathognomonic of active trachoma. Their appearance is absolutely characteristic, and they cannot be confused with such other limbal hypertrophy as occurs in the limbal variety of vernal catarrh. When the limbal follicles absorb they leave behind cicatricial remains known as Herbert's pits.[11] These pits appear as clear areas in the serrated limbal margin and are best demonstrated by retroillumination. Like the limbal follicles their demonstration is an unequivocal indication of preexisting trachoma. Unfortunately they occur in not more than 50 per cent of the cases of trachoma.

Limbal Hypertrophy of Vernal Catarrh.—The papillary excrescences of vernal catarrh involve the temporal and nasal areas of the limbus predominantly but occasionally form a ring around the entire cornea. This limbal hypertrophy when typical is pathognomonic of the limbal variety of vernal catarrh, but in cases of mild disease it is sometimes confused with the limbal hypertrophy occurring in phlyctenular conjunctivitis or even with that of episcleritis. When chalky concretions, known as Trantas' spots,[12] occur in the limbal hypertrophy, however, it may be considered diagnostic of vernal catarrh.

Extension of Limbal Vessels.—Extension of limbal capillary loops into the cornea is characteristic of incipient trachoma and may occur in cases of severe trachoma as early as one week after onset. This extension in trachoma always occurs first at the upper part of the limbus and is always much more prominent there than at the lower part. When combined with punctate epithelial staining and subepithelial infiltrates, more pronounced in the upper half of the cornea than in the lower, the diagnosis of trachoma is almost mandatory.

Extension of limbal capillary loops may of course occur in other conditions besides trachoma, such as phlyctenulosis, riboflavin deficiency,[13] marginal infiltrates, herpes corneae, and even occasionally in vernal catarrh, but the vascularization is usually irregular in these conditions and is not localized predominantly in the superior part of the limbus, as in trachoma. These conditions also lack the upper corneal infiltration and punctate epithelial staining which is characteristic of trachoma. It should be remembered that in older persons arcus senilis is usually accompanied by penetration of limbal capillary loops beyond the normal boundary of the limbus.

A wide limbus is sometimes confused with corneal vascularization, but if particular attention is paid to the corneal boundary of the limbus no such mistake will be made. The corneal border of the limbus, best seen by direct focal illumination, appears as the slightly serrated border of the limbal opacity. Gross extension of capillary loops beyond this line can be considered pathologic.

Marginal Infiltrates and Ulcerations.—Isolated marginal corneal infiltrates, especially when accompanied by punctate epithelial staining, are almost diagnostic of staphylococcic conjunctivitis,[14] although they may in rare instances also be seen in diplobacillary, Koch-Weeks, and streptococcic conjunctivitis. Scattered subepithelial infiltrates involving the upper half of the cornea predominantly always suggest trachoma. The occurrence of grossly visible round subepithelial infiltrates tending to involve the pupillary area is almost pathognomonic of epidemic keratoconjunctivitis.[15] Marginal infiltrates of an extensive nature and tending to form rings concentric with the limbus always suggest endogenous infections. Such ring infiltrates are seen in endogenous conjunctivitis of various sorts and with special frequency in the keratoconjunctivitis which occasionally accompanies bacillary dysentery.

Punctate Epithelial Staining.—The diagnostic value of punctate epithelial staining is in general not sufficiently realized. It is perhaps most frequently seen in staphylococcic conjunctivitis, in which it tends to involve the lower half of the cornea predominantly. In this condition the punctate staining is fine and the points never become confluent. Similar punctate staining in conjunction with formation of filament and irregular confluent lesions immediately suggests keratoconjunctivitis sicca;[16] the simultaneous occurrence of mucus secretion sticking to the corneal surface gives a picture pathognomonic of the disease. The punctate staining of trachoma is exactly like that of staphylococcic conjunctivitis except that it always involves the upper half of the cornea predominantly. The punctate staining of superficial punctate keratitis differs strikingly from the previously described types in that only a limited number of staining areas occur and that each of these is formed by a group of punctate staining points which can readily be resolved by high power examination. Punctate staining similar to that occurring in staphylococcic conjunctivitis is occasionally observed in eyes which have received radiation.

COMMENT

Certain of the previously discussed clinical findings are individually pathognomonic of a number of etiologic types of conjunctivitis. Thus the limbal follicles or their cicatricial remains (Herbert's pits) are in themselves unequivocally diagnostic of trachoma. Of similar importance are the chalky concretions (Trantas' spots) in the limbal excrescences of vernal catarrh, and the pavement block-like papillae on the upper tarsal conjunctiva in palpebral vernal catarrh.

Most conjunctival changes, however, are not in themselves individually pathognomonic but are only suggestive of certain causal types. Examples of such nonpathognomonic changes include punctate epithelial staining of the cornea, the conjunctival follicle and extension of limbal vessels into the cornea. But when several such changes occur simultaneously, they may together point to a specific cause. Thus the extension of limbal vessels, when combined with punctate epithelial staining, subepithelial corneal infiltrates and upper tarsal follicles, gives a composite picture diagnostic of trachoma. In the same way punctate epithelial staining of the cornea, in itself not pathognomonic, is clearly indicative of staphylococcic infection when combined with chronic conjunctival inflammation and lesions of the lid margins.

SUMMARY AND CONCLUSIONS

There are a number of clinical signs, both gross and biomicroscopic, which are of diagnostic importance in conjunctivitis. Changes in the regional lymph nodes, the lid margins, the limbus and the cornea are of almost equal diagnostic importance with those occurring in the conjunctiva itself. By clinical examination alone it is possible to identify many of the various etiologic types of conjunctivitis. When these clinical observations are correlated with cytologic and bacteriologic studies, the cause can be determined in a high percentage of cases.

ABSTRACT OF DISCUSSION

Dr. James H. Allen, Iowa City: Dr. Thygeson has provided a logical and practical basis for beginning the differential diagnosis of inflammatory and infectious diseases of the eye. Under Dr. Thygeson's influence my colleagues and I have used this method not only for diagnosis but for teaching our residents. We find that it is highly stimulating to the residents and that it simplifies teaching. It is unfortunate that time did not permit Dr. Thygeson to extend the differential diagnosis which he uses to its logical completion. The beginning is the differentiation on the basis of a single manifestation—preauricular adenopathy, for instance. The extension, then, is the division into and differentiation of follicular conjunctivitis, nodular conjunctivitis, the ulcerative variety, and so on.

DR. TRYGVE GUNDERSEN, Boston: Conjunctivitis alone gives rise to few symptoms except those associated with swelling of the conjunctiva, interference with lacrimal drainage and increased secretion of mucus, pus and tears. These in order cause a sense of fulness around the eyes, some tearing and, lastly, agglutination of the lids, especially on awakening. When the cornea becomes involved, new symptoms appear. Punctate keratitis, such as caused by Staphylococcus toxin, causes pain—occasionally a definite deep-seated ache in the globe. Since it is not uncommon for the superficial punctate lesions to heal during the day with the natural cleansing of the conjunctiva and the washing away of the bacterial toxins, the symptoms also disappear. Therefore, a symptom of diagnostic importance is ocular pain, most severe in the early morning and lessening during the day. In contrast to ocular pain which is most severe on arising and less severe as the day goes on, there are painful sensations which behave in a reverse manner. For instance, in keratoconjunctivitis sicca the healing of the corneal defects occurs during the night, when the lids are closed and the cornea is kept normally moist and lubricated. Therefore the painful sensations of heat and dryness of which these patients complain increase during the day. This is particularly true on hot, dry and windy days. Itching is a symptom which is most helpful for the ophthalmologist to elicit and should never be overlooked when offered spontaneously by the patient. To me it invariably and exclusively indicates allergy. The victim of hay fever knows this. No patient with active vernal catarrh fails to give itching as his most troublesome complaint. It exists even in conjunctivitis due to the prolonged use of atropine and less frequently of physostigmine salicylate and pilocarpine. The cause of the itching has never been clearly defined, but I believe that it may be due to—or at least it is always associated with—the corneal stippling which Dr. Thygeson has described as fine punctate staining. This is an important type of corneal change to recognize as an entity. Not all the stippled points do stain with fluorescein sodium. At the Massachusetts Eye and Ear Infirmary we have accepted Vogt's term, "keratitis epithelialis disseminata," and until a better term is offered, I suggest that this descriptive one be used. It is common. It always exists on the corneas of patients who have active vernal catarrh, and frequently on the corneas of patients with other allergic conditions of the eyes. I offer it as possibly the direct cause of ocular itching.

DR. I. S. TASSMAN, Philadelphia: The oculoglandular syndrome of Parinaud was referred to as leptotrichosis, which is what we always understood it to be. I wonder if Dr. Thygeson could add anything to clarify the relationship of the virus of lymphogranuloma venereum to the causation of Parinaud's oculoglandular syndrome.

DR. PHILLIPS THYGESON, San Jose, Calif.: I was particularly interested to have Dr. Gundersen discuss the diagnostic value of the various subjective symptoms of conjunctivitis. Dr. Allen brought out the important interrelationship of the various signs and symptoms of conjunctivitis and showed that whereas one sign alone may not be diagnostic, the combination of two or more signs may be so. This is well brought out in oculoglandular conjunctivitis, in which the presence of a visibly swollen preauricular node is not in itself diagnostic but, when combined with small areas of necrosis in the conjunctiva immediately points to the etiologic entity of leptothricosis conjunctivae (Verhoeff). There seem to be two schools of thought on the oculoglandular syndrome of Parinaud. Dr. Verhoeff, I believe, is of the opinion that there is only one Parinaud conjunctivitis, which is the leptothrichosis conjunctivae, in which he discovered the causal agent. The late Dr. Sanford Gifford strongly urged the use of the term "oculoglandular syndrome of Parinaud" to include all the various etiologic types of conjunctivitis characterized by the occurrence of large swollen preauricular glands. In this syndrome would be included such etiologic entities as tuberculosis of the conjunctiva, lymphogranuloma venereum conjunctivitis, syphilis of the conjunctiva, etc. There are ten or more entities which would be included in this group. I personally prefer the term "oculoglandular syndrome of Parinaud" for use in describing a conjunctivitis of this type, at least until the causation has been determined, which in many cases will be found difficult or impossible.

SYMPATHECTOMY FOR PERIPHERAL VASCULAR SCLEROSIS

GEZA de TAKATS, M.D.
and
MATTHEW H. EVOY, M.D.
Chicago

Peripheral vascular sclerosis is the overwhelming single cause of deficient arterial circulation in the lower extremities. Four grades of this disease can be recognized, and it was pointed out in a previous study[1] that any therapeutic measure must be evaluated on the basis of these four groups and their response toward the method under scrutiny.

In this study lumbar sympathectomy has been employed alone or in combination with various types of amputation in rigidly selected patients. Our purpose here is to discuss the selection of cases, the surgical approach and the results together with an interpretation of the observations. The previous literature on the subject has been summarized elsewhere.[2]

MATERIAL STUDIED

The series consists of 57 carefully selected cases, and we shall group them according to the severity of the disease as outlined in a previous paper.[1]

GROUP 1.—These patients have diminished or absent pulsations of the foot or lower leg. The skin is warm, and the color of the feet is normal. They can walk a distance of 2 to 6 blocks without pain. Comparatively few patients are seen in this series, since their symptoms increase insidiously and seldom send them to seek medical advice. In hypertensive persons or patients suffering from angina pectoris the symptoms of claudication are masked, overshadowed or prevented by the appearance of ischemic syndromes elsewhere.

Lumbar sympathectomy has been performed in 18 such patients. The improvement in walking ability in some has been dramatic. The average increase in ability to walk without claudication has been from 3 blocks to 9 blocks; however, a 51 year old mail carrier increased his walking ability to an unlimited distance and a 38 year old amusement park operator could walk for three hours continuously without pain.[2] These persons have been restored to their full earning power. Another group just about doubled their walking ability, and in 2 patients there has been no improvement in claudication, although the foot and lower leg has become warm and dry. This immediately raises the question whether claudication can be relieved at all by sympathectomy, a question to be taken up later.

GROUP 2.—The feet of the patients in this group are pulseless, and their ability to walk without pain is reduced to below 2 blocks. However, trophic changes may still be absent although the feet are cold and dry and a single toe is often cyanotic. A cold and moist foot, incidentally, always gives a better prognosis because such patients exhibit a heightened sympathetic tone, the release of which warms up their skin. In

[2] de Takats, G.; Fowler, E. F.; Jordan, P., and Risley, T. C.: Sympathectomy in the Treatment of Peripheral Vascular Sclerosis, J. A. M. A. **131**: 495 (June 8) 1946.

such patients walking ability remains unimproved. However, the cyanosis may disappear and a pregangrenous leg has been converted into a warm, dry extremity which remains painless on definitely limited walking. Improvement in walking ability within six to twelve months aided by a suitably set rhythmic constrictor can occur. The nonsympathectomized leg may deteriorate faster and in 2 instances has come to amputation, whereas the sympathectomized leg maintained its viability. Of 22 patients in this series only 1 required an amputation.

GROUP 3.—There is pain at rest and intractable ischemic neuritis in this group. Walking may be less painful or even offer relief when rest in bed is difficult. When the foot is ice cold and when arteriolar obstruction and capillary paralysis are obvious from the pronounced dependent rubor sympathectomy is of no use and may precipitate [illegible] ɔrm, however, in which the pulseless foot is hot and osteoporotic and tolerates even mild heat but poorly, a causalgic state exists,[3] and after a satisfactory response to sympathetic block a sympathectomy has averted amputation. This is a small but definite group of 6 patients, 3 of whom were diabetic and 2 alcoholic, an indication that their ischemic neuritis was superimposed on a neuropathy of other origin.

GROUP 4.—These patients exhibit ulceration and gangrene of the digits or parts of the foot. The lesion is dry and not too painful. There is no evidence of infection. The popliteal pulse is absent, and possibly the femoral is also absent. Supracondylar amputation used to be the surgical procedure of choice in these patients at the level of positive histamine flares. However, a sympathetic block may so shift the level of circulatory efficiency that a lower leg or a midmetatarsal amputation can be tolerated. This is an important group, since patients can be discharged with a healed stump below the knee or at metatarsal levels who would never tolerate such an amputation without sympathectomy. There are, of course, certain precautions to be taken in performing these amputations. The surgical operations are performed by avoiding flaps, by never suturing anything else but skin, by avoiding the slightest tension and by draining through a dependent stab wound. Traction is never used, nor is snug elastic compression advisable, but a loose stump dressing is applied and left alone for twelve to fourteen days. We mention these details because the traumatic amputations in the Armed Forces required an entirely different type of management, which is not applicable to this group. Eleven patients are in this series. Their number can be greatly increased but is limited by age, general debility or general cardiovascular damage.

SUMMARY OF RESULTS

A tabulation of the four groups reveals the following: In the first group walking ability was not improved in 2 of 18 patients; in the second group pain was unrelieved and gangrene developed in 1 of 22 patients; in the third group pain at rest was relieved and amputation averted in all 6 patients. In the fourth group below the knee or midmetatarsal amputations healed in 10 of 11 patients. Of the total 57 patients, then, 53 benefited considerably whereas 4 failed to benefit from the surgical operation. Considering the degree of vascular involvement, this is an encouraging performance.

THE TECHNIC OF LUMBAR SYMPATHECTOMY

Recently I have described our method of muscle-splitting, extraperitoneal approach in the surgical clinics.[4] In these sclerotic, handicapped, elderly patients this is the simplest and least injurious surgical operation, performed under spinal anesthesia in from twenty-five to forty-five minutes, with early ambulation and discharge from the hospital after a week to ten days. When bilateral sympathectomy is needed, the two stages of the operation are performed a week to ten days apart. The transperitoneal approach is used only in certain infrequent instances; when it is important to remove the first ganglion because of an iliofemoral occlusion the lumbar approach may be used, which is easier on the surgeon but more difficult for the patient.

There has been no mortality in this group and none in several hundred lumbar sympathectomies performed for other causes. One severe infection which developed in a wound had to be drained; the patient made a good recovery. The infection was traced to a persistent streptococcus carrier among the instrument nurses.

COMMENT

As Hueper [5] pointed out, a fatalistic attitude prevails toward the prevention and treatment of arteriosclerosis, since the theory of senescence still obtains in the minds of most physicians. In his review Hueper has listed a multiplicity of factors capable of producing a similar tissue response in the arterial tree. From the surgeon's point of view peripheral arteriosclerosis is often encountered as a segmental, patchy disease responsible for ischemia, which need affect other organs only slightly. The first object of study, then, is to examine the extent of vascular involvement in vital organs. This is accomplished by a study of eyegrounds, the electrocardiogram, a 2 meter chest film and a concentration dilution test. Cerebral, cardiac or renal involvement of severity obviously rules out any surgical attempt to improve circulation of one or two lower extremities. Certainly a patient is not a candidate for sympathectomy if he has had a stroke or a myocardial infarct or if he exhibits decided renal impairment.

Three factors may be considered without argument as being important in the causation and progression of arteriosclerosis, namely: diabetes, lipemia and hypertension. None of these have to be present, but when they are suitable measures must be undertaken to control them. Diabetes is not a contraindication to lumbar sympathectomy; in fact, some of the severe burning paresthesias have been seen to be relieved after this surgical operation (group 3 of our series). But of course its preoperative and postoperative control is obviously necessary. Lipemia, with or without hyperglycemia, has been relatively frequently encountered; the literature on attempts to control it is vast and need not concern us here.[6]

The point should be made, however, that the reduction of blood cholesterol levels of over 250 mg. per hundred cubic centimeters prevents further atheromatous deposits and is frequently possible with high protein, low fat diets, thyroid, lipocaic or methionine.

The factor of vascular tension in the production of vascular sclerosis has been especially stressed by

Moschcowitz.[7] In our study of hypertensive patients, in which over 250 patients have been subjected to dorsolumbar sympathectomy, the involvement of the peripheral vascular tree obviously runs in fair parallel with organic lesions elsewhere in the body, particularly with those of the coronary arteries. We wish to stress the hitherto neglected point, however, that even the normotensive patient carries a higher peripheral resistance in the lower extremities when he sits or stands. This postural hypertension in the lower extremities favors the deposition of subintimal atheromatous plaques, which are notoriously rare in the upper extremities. Certainly this is true in the cholesterin-fed upright rabbit.[8]

The control of postural hypertension in the erect human being by means of sympathectomy is of great importance in the prevention of atheromatous deposits. The accompanying chart indicates that the great shift in peripheral resistance which always occurs when man stands up can be mitigated if not completely abolished by sympathectomy. This is true both in the normotensive and in the hypertensive person. The pulse waves become smaller, the peripheral resistance declines and the mechanical strain on the vascular tree of the standing position is dampened. The drop in skin temperature, which is most pronounced in the feet when the individual is erect, is also abolished.

That thermal stimuli, such as a cold spray or a cool draft are also ineffective in the sympathectomized limb is too well known to receive much comment. That it is a potent factor in the symptomatology of vascular disease is known to those patients who seek a subtropical climate for the relief of their symptoms. While the sympathectomized limb may cool off on direct exposure to cold, it regains its previous temperature much faster when its vasomotor supply is cut.[2]

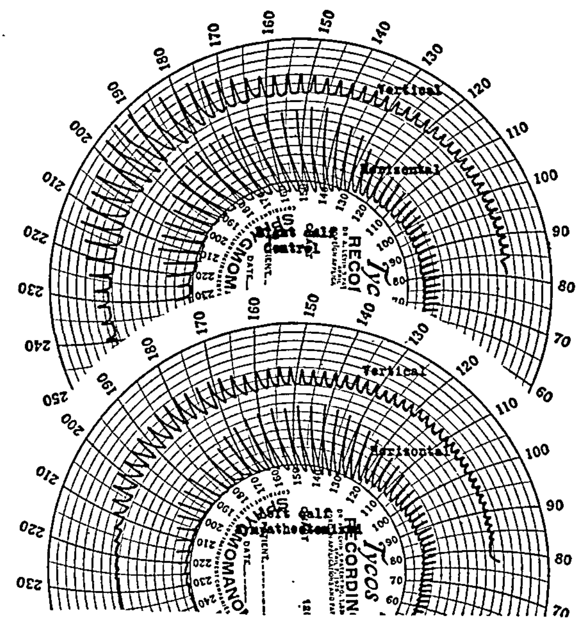
A third factor affecting the flow of blood is the central nervous factor. Emotional stimuli, anxiety, hostility and mental arithmetic may cause vasoconstriction or vasodilatation, usually the former. Any of these effects is abolished by sympathectomy. The sympathectomized limb of the patient suffering from peripheral vascular sclerosis is freed from postural, reflex, thermal and emotional vasoconstriction. The time-honored advantages of rest in bed in the horizontal position and of even warm climate or mild heat and freedom from worry, which exert a beneficial influence on peripheral circulation, are all suddenly accomplished by lumbar sympathectomy.

The utilization of an intermittent venocapillary stretch, which is a widespread and extremely useful method of treating peripheral vascular disease, is greatly facilitated by sympathetic denervation, since constrictor reflexes originating from this procedure are abolished. The five points in favor of lumbar sympathectomy on the lower extremity may then be briefly summarized as follows:

1. The extremity warms up faster and cools more slowly on direct exposure. Reflex effects of heat and cold are ineffective.
2. The high vasoconstrictor tonus in the sitting or standing position is abolished.
3. Vascular exercises such as intermittent venous hyperemia are more effective.
4. Any cross stimulation between sympathetic and demyelinated sensory fibers is abolished.
5. During effort the sympathectomized extremity will not cool off; on the contrary, it may become warmer.

The 57 patients whose cases are reported herein are of course just a drop in the bucket to the staggering number of middle-aged men for whom such surgical intervention might become necessary. It seems that if claudication becomes a handicap or an alarming symptom to the patient he has little of the physician's therapeutic armamentarium from which to choose. The continuous use of intermittent venous hyperemia in the home[9] for a period of many months and years has definite value but is lengthy and time-consuming, and the surgical operation has accomplished in one week what the constrictor may do in many months.

Prolonged sojourn in subtropical climates is known to be helpful, but the cost is prohibitive for many. Rest in bed for many weeks decreases vasomotor tone and is often the only possible course before amputation. As pointed out elsewhere,[2] the sympathectomized limb with its vasomotor palsy offers the advantages of horizontal rest in bed, warm climate and freedom from worry, as far as its effect on the extremity is concerned.



Oscillometric graphs from the right and left calves of a patient whose left lower extremity has undergone sympathectomy. Note that on the nonsympathectomized extremity the diastolic pressure rose from 100 to 160 mm. of mercury when the patient stood up. On the sympathectomized side there is no increase in the height of the pulse waves at higher levels and peripheral resistance did not change in the vertical as compared with the horizontal position. This graph indicates the protective action of lumbar sympathectomy from the postural hypertension of the lower extremity.

Frequently the cramping on walking gives way to fatigue in the calf or the numbness in the foot and toes becomes prominent when claudication improves. This brings into focus the much debated question whether vasomotor paralysis really affects the circulation of the muscles and, indirectly, their metabolism. Disuse of the muscle itself leads to atrophy and often muscle fatigue, which is not muscle cramp, is responsible for the residual symptoms. All this needs to be explained to the patient, who expects complete relief and may be disappointed.

SUMMARY

A group of 57 patients with vascular sclerosis of the lower extremities has been studied. If after preliminary block of the lumbar sympathetics the temperature of the digits rose, walking ability improved and generalized vascular involvement was not extensive a lumbar sympathectomy was performed. In one group of patients this operation resulted in a dramatic increase in walking ability; in a second group amputation was averted; in a third group intractable neuritic pain of the causalgic type was benefited, and in a fourth group amputation could be performed at a lower level. In rigidly selected cases of peripheral arteriosclerosis, lumbar sympathctomy has proved to be a method of great value.

ABSTRACT OF DISCUSSION

Dr. Felix Pearl, San Francisco: In the early 1930's, the use of sympathectomy in the treatment of arterial insufficiency of the extremities from degenerative arterial disease was considered almost a surgical crime. Today, we have heard Dr. de Takats report a whole series of such cases. In the clinic at Mt. Zion Hospital we were long ago impressed with the idea that this operation was nonspecific in character, producing increased circulation irrespective of the underlying process. With satisfactory vasoconstriction there is no reason why sympathectomy should not be effective in the treatment of degenerative arterial disease. We have performed this operation on 50 extremities. In almost all instances it was performed by the muscle-splitting extraperitoneal approach, which has been found eminently satisfactory. All but 3 patients had excellent responses to vasomotor paralysis and were considered good subjects for the operation. Of those that had a good element of vasoconstriction, not 1 patient had an amputation of any kind. In a similar period, approximately 75 low thigh amputations were performed for degenerative arterial disease in nonsympathectomized extremities. In about one third of the sympathectomized extremities pulses were improved in volume or were felt postoperatively where none were felt before operation. In a similar number of patients there was well defined relief from claudication. In many the claudication and postural color changes subsided or disappeared. The vasodilatation indicated by the preopeiative study followed the surgical procedure in nearly every instance and persisted for extended periods; in 1 case as long as eight years. Our cases of ulceration or gangrene have had insufficient vasoconstriction to warrant surgical intervention. Otherwise, our results have closely paralleled those of Dr. de Takats. Early in our experience we discarded paravertebral block because of the inability always objectively to determine the successful block and its unreliability in estimating relief from pain. We replaced it with block of peripheral mixed nerves, the completeness of which was evidenced by the anesthesia produced; in over 400 such blocks the method has demonstrated its value. Patients who have already lost one leg are urged to have their remaining extremity sympathectomized if signs of degeneration are present even though it is symptomless. Sympathectomy in degenerative arterial disease is performed to increase the circulation for preservation of the extremity, to relieve symptoms, to stop the pathologic process. Our statistics show that the surgical operation preserves the extremity; but the patient should be warned in advance that his claudication may not be relieved. Heuper's work suggests that sympathectomy also favorably affects the course of vascular degeneration of the lower extremity. Dr. de Takats has been much too conservative in estimating some of his results. For example, in group 1 he lists the results in 2 patients as failures because their claudication was not improved. Yet their extremities showed postoperative vasodilation. I do not consider these failures because they have probably protected the patients against subsequent ulceration or gangrene.

Dr. Alton Ochsner, New Orleans: After this presentation most of us will want to have a sympathetic block before starting our trek through the exhibits or walking up some of the San Francisco hills. The section is indebted to Dr. de Takats for calling attention to this important therapeutic aid. As Dr. Pearl has said, we have been in the habit of thinking of vasodilatation as being limited and applicable only to those cases in which there has been little organic disease. From our experience we are convinced that in even the degenerative cases a vicious circle is set up; that this is less than it is in the vasospastic organic lesions, but that even in these there is a vicious circle which is set up, with the organic obliteration tending to produce vasospasm. We are advocates, as Dr. de Takats is, of the value of the sympathetic block as determined with procaine hydrochloride. We feel that although objective manifestations, such as those obtained by means of the Burch plethysmograph, or oscillograph, are of value; however, the functional result is even more important. If the patient can walk better and farther after the block he is likely to be benefited by sympathectomy. We have not had the difficulty that Dr. Pearl apparently has had in getting a satisfactory block because we use four needles at the first, second, third and fourth lumbar vertebral levels. It is of importance, too, in using sympathectomy, as Dr. de Takats has emphasized, to consider the conservation of extremities. At the present time, in our group, under the direction of Dr. Champ Lyons representing the surgical service and Dr. Guy Caldwell of the orthopedic service we have instituted a program which is, as far as we are concerned at least, very conservative. Whereas we used to do amputations in many of these patients who were having difficulty with their extremities, now by means of sympathetic ligation in a preparatory way, much less radical procedures can be undertaken with the preservation of a good deal of the extremity, which was not possible before the use of sympathetic surgical procedures.

Dr. Robert Katz, New Orleans: I should like to call attention to a very important part of Dr. de Takat's paper, that is, the economic importance of the relief of pain and symptoms. Vascular sclerosis has been perhaps the most terrifying disease of the aging population here in America. Dr. Alton Ochsner and his school, Dr. de Takats and his school and other men throughout the nation have demonstrated what has been done for the relief of acute pain by the simple procedure of sympathectomy. However, there are instances in Dr. de Takat's classification where sympathectomy fails. In this particular group of patients, there is a new nonsurgical method based on a therapeutic drug of one hundred years of experience, namely, U. S. P. ether, used under the name of diethyl oxide because of the adverse psychologic effect produced in patients by mention of the term "ether." I have recorded through the Touro Infirmary of New Orleans and the U. S. Marine Hospital, as consultant, 100 already published cases of peripheral disease, mainly vascular sclerosis treated successfully with diethyl ether given intravenously for a course of twenty-four treatments. In this work I have had the help and the encouragement of Dr. Rudolph Matas. The results appear to be helpful in those cases where sympathectomy is not of benefit or is not indicated. This method has been used with a success of approximately 85 per cent, including the bad results of the initial experimental stage. Sympathectomy in selected cases offers a quicker relief of pain; sympathectomy offers a quicker way to get the man back to economic stability. However, we still have another nonsurgical therapeutic tool, intravenous diethyl ether. It is simple. The safety record is unblemished; no patients have died, no patients have been put into an anesthetic sleep. It is absolutely safe. I hope that the profession, the surgeons especially, will consider this method. We have a new tool, a solution of 2½ per cent diethyl oxide (diethyl ether) administered intravenously in 1,000 cc. isotonic solution of sodium chloride, to implement already established collateral circulation. Perhaps a better one may come along later, but at least a beginning has been made.

DR. GEZA DE TAKATS, Chicago: I am greatly indebted to the discussants and would like to reiterate that it was Dr. Pearl who first drew our attention to the so-called angiospastic claudication, that is, to the type of people who develop angiospasm while walking. It is also his surgical approach of anterolateral muscle-splitting extraperitoneal incision, which can be done in twenty-five to thirty-five minutes under spinal anesthesia, that we have been using. In this series and in another series of sympathectomies performed for other types of peripheral vascular disease, and which now goes into several hundreds, we have as yet had no mortality. Dr. Ochsner has already answered our reaction to the paravertebral block versus peripheral block, in trying to estimate the amount of vasomotor tonus. When one performs a peripheral nerve block, of course one develops a sensory anesthesia and thus does not get as much information about the expected pain-relief resulting from sympathectomy. It is also true, however, that one who is inexperienced in paravertebral block may so flood the lumbosacral plexus that sensory anesthesia results, or one can even get a spinal anesthesia. It is very important, as Dr. Ochsner has already stated, to learn the technic of this simple and useful procedure of paravertebral sympathetic block. Unquestionably there are patients with a high, medium or low vasomotor tonus. That is inherent in their constitution. There have been some efforts made to measure this, but it is certainly true that a patient with a high vasomotor tonus plus arteriosclerosis is going to get a far better result from sympathectomy than a patient with a low vasomotor tonus. Lumbar sympathectomy, of course, is not a cure-all for peripheral vascular sclerosis. I tried to emphasize that this operation is applicable to only a very limited number of patients. Many of them, of course, have acute lymphangitis, many have massive gangrene and many are toxic. It would be folly to waste time on conservative therapy. They need amputation; they need amputation in a hurry, possibly a two stage amputation. Sympathectomy is really not only an early therapeutic but a preventive measure to ward off later disaster.

A CONTRIBUTION TO THE STUDY OF ECLAMPSIA

Consideration of Two Hundred Cases

FRANK E. WHITACRE, M.D.
WALTER M. LOEB Jr., M.D.
and
HENRY CHIN, M.D.
Memphis, Tenn.

With the assistance of T. S. Hill, M.D., and Hudson Jost, Ph.D., on the electroencephalographic tracings

A final classification of the toxemias of late pregnancy has not yet been made, nor can it be made until etiologic factors are more definitely known. An attempt at uniformity in terminology was made by the suggested classification of toxemias of pregnancy by the American Committee on Maternal Health (1939), and this classification has been widely adopted. A voluminous literature has arisen and individual volumes have been written on this complicated problem. Therefore a review of the literature is not attempted herein. This paper limits the term toxemia of pregnancy to include only preeclampsia and eclampsia, because renal disease of pregnancy and hypertensive disease are other entities.

In the past the most plausible theory has been that this condition is the result of a toxin circulating in the blood stream which upsets the water balance and causes changes in the liver, directly or indirectly, and degenerative changes in the kidneys and that convulsions occur because of direct action of a toxin on the cerebral cortex or because of intracranial pressure due to edema. We would rather define this disease of pregnancy as probably related to nutritional deficiencies and characterized by a syndrome of symptoms and distinct pathologic lesions which are associated with angiospasm.

MATERIAL

In the literature many factors of doubtful importance are mentioned. This has led us to review our cases to determine if some of these factors are really significant. The present report comprises data on 100 consecutive eclamptic patients from the obstetric and gynecologic service of the Peiping Union Medical College Hospital, Peiping, China, observed during the years 1935 to 1941. These cases are compared with those of 100 consecutive eclamptic patients from the department of obstetrics and gynecology of the University of Tennessee at Memphis, observed during the years 1941 to 1945 (table 1). Henceforth the group from Peiping will be designated group 1 and that from Memphis group 2. The 100 cases of women with convulsive seizures in group 1 occurred among 4,553 deliveries, giving a hospital incidence of 2.2 per cent, while in group 2 the same number of convulsive patients were encountered in 8,797 deliveries, giving a hospital incidence of 1.2 per cent. The highest seasonal incidence in both groups was in the summer and autumn, and the age incidence was practically the same. Inasmuch as each group consists of 100, each patient represents 1 per cent. All the patients from Peiping were Chinese, while in the Memphis series 96 were Negro and 4 white. The assertion by numerous authors that eclampsia is a disease of primiparas is borne out by our cases; in the Chinese series 75 were primiparas and 25 multiparas, while in the Memphis group 72 were primiparas and 28 multiparas. In group 1 there were 73 who had not previously been seen in the outpatient clinic, while in Memphis 55 were admitted to the hospital without previous treatment, which emphasizes the value of prenatal care.

In regard to the appearance of convulsions in relation to the labor, 75 of group 1 were antepartum, 10 intrapartum and 15 postpartum, while 77 of group 2 were antepartum, 6 intrapartum and 17 postpartum. The stage of gestation conformed to the reports of others, as 98 cases in group 1 and 99 in group 2 occurred after the sixth month of pregnancy.

The uncorrected mortality rate shows maternal death in 20 and fetal death in 36 cases of group 1, while in group 2 maternal death occurred in 14 and fetal death in 20 instances (table 2). In group 1, 53 patients were treated by means of morphine and chloral hydrate. There were 4 cesarean sections; 2 of these patients died. The total of deaths among the 53 mothers was 14. Forty-seven mothers were treated by the use of magnesium sulfate solution given intramuscularly, barbiturate preparations and intravenous hypertonic dextrose; in general they were given the combined treatment recommended by Dieckmann.[1] There was only 1 cesarean section. Of the 47 mothers, 8 died, while in group 2 in which 58 were treated by the combined method and 5 were safely delivered by cesarean section there was a total of 10 deaths. Forty-two patients in group 2

Dr. Henry Chin was formerly of Peiping, China.

Read before the Section on Obstetrics and Gynecology at the Ninety-Fifth Annual Session of the American Medical Association, July 3, 1946.

From the Departments of Obstetrics and Gynecology of the Peiping Union Medical College, China, and the University of Tennessee College of Medicine.

[1] Dieckmann, W. J.: The Toxemias of Pregnancy, ed. 1, St. Louis, C. V. Mosby Company, 1941, p. 428.

were treated by the combined method in addition to the use of veratrum viride. Morphine was not used. There were 7 cesarean sections; 1 death occurred. The total maternal deaths among the 42 mothers was 4. In general, one may say that the results of treatment improved in direct proportion to the more conservative methods of management. There were only 5 cesarean sections in group 1 with 3 deaths and 12 cesarean sections in group 2 with 1 death. However, these surgical interventions were carried out in the latter half of each series after the disease had been brought under control, which emphasizes the importance of this factor.

TABLE 1—*General Summary*

	Group 1, Peiping, China, 1935 1941	Group 2, Memphis, Tenn., 1941-1945
Consecutive eclamptic patients	100	100
Deliveries........	4,553	8,797
Per cent	2.2	1.2
Season		
Spring	14	17
Summer	28	37

Fetal (4 were less than 2,000 Gm.) ..	20

The results of the chemical analyses performed on the blood in all cases are in accord with those in previous reports. In group 1 the average level of nonprotein nitrogen was 34 mg. and that of uric acid, 6.4 mg. per hundred cubic centimeters of blood, while in group 2 the findings were 32 mg. and 6.4 mg., respectively.

Consideration of the two groups of eclamptic patients totaling 200 cases provides some interesting, although for the most part negative, observations. The fact that the patients in these two groups live on opposite sides of the earth and that one group comes from a cold, dry climate and the other from a moist, warm climate made no difference, nor were differences due to race or color significant. The incidence with reference to parity was almost identical. In both groups the disease occurred among the underprivileged or indigent, who could be expected to have nutritional deficiencies.

From May 1, 1941 to Dec. 31, 1945, which is the time considered in group 2, there were 23,352 deliveries in the private hospitals of the city of Memphis, Tenn., and in 68 of these the patients had eclampsia. This is an incidence of 0.29 per cent. Most of the 68 patients were on the charity services of the hospitals.

PATHOLOGY

When the liver of a woman who died in eclampsia is cut across, the cut surface may feel granular. Small, elastic walls of the blood vessels have retracted, and the protruding thrombi provide the granular sensation. The increased clotting properties of the blood are probably concerned in this mechanism. Ischemic necrosis and hemorrhage are apt to be found in the portal spaces. Thromboses of the radicles of the portal vein have long been considered important in this mechanism. However, angiospasm which affects the hepatic arterioles may also be concerned.

Lesions of the kidney are not constant and have been considered either primary or secondary in this disease. The latter view is probably correct. Various degrees of nephritis occur but are not constant. Of importance is the frequency with which the glomerular tuft is found empty, which would explain the suppression of urinary excretion on the basis of angiospasm. The observation of occasional thrombi in the vessels leading to the glomerulus is also explained on the same basis. Inasmuch as the blood supply of the collecting tubules is secondary to that received by the glomerulus, it is not surprising that th[illegible] iges are first found in the tubules. [illegible][2] have shown by experimental evidence that renal ischemia is concerned with this disease, and this is in accord with clinical observations which are explained as the result of angiospasm.

The brain shows varying degrees of edema and hemorrhagic foci. Fatty degeneration of the heart and other organs is a secondary manifestation.

ETIOLOGY

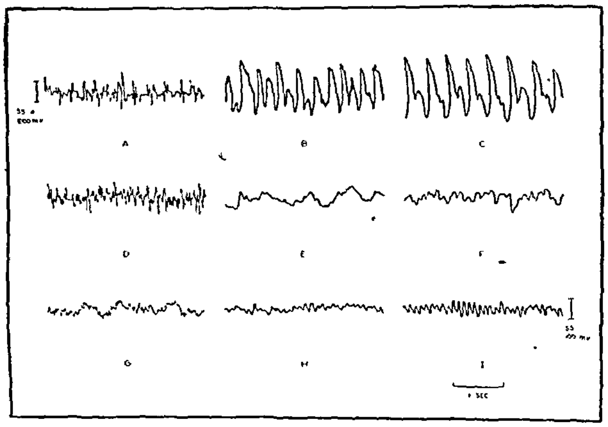
The cause of eclampsia is not known. Clinical observation and research have yielded sufficient information, however, to materially change our concept in this regard. The ophthalmologists were first to observe that the small blood vessels in the retina were constricted in the presence of preeclampsia and eclampsia. It had long been known that the volume of urine was decreased and that the degree of suppression corresponded to the severity of the disease. There were those who recognized that the decrease in the volume of urine could also be explained on the basis of angiospasm. It is probable that this constriction of the arterioles is generalized not merely in the eye and kidneys but throughout the entire body. This would account for the rise in blood pressure, which is either gradual and prolonged in the preeclamptic stage or sudden when it precedes convulsions. It had also been noted that the duration of hypertension might be more important than the severity of the disease, that is, the patient who had an elevation of blood pressure which was existent for several weeks might suffer permanent renal damage, even though convulsions did not occur. However, in a rapidly developing toxemia which lasted only a few days, even though attended with convulsions, there might be no permanent damage to the kidneys. This latter observation may have led early investigators to conclude that the disease conferred an immunity.

---

[2] Dill, L. V., and Erickson, C. C.: Effect of Constriction of the Renal Arteries in Pregnancy and in Certain Endocrine States of Rabbits, Arch. Path. **31:** 68 (Jan.) 1941.

Many have believed that the placenta produces a pressor substance, but it could be reasoned equally as well that a pressor substance is always present during pregnancy but that a counteracting removal of the pressor substances is absent or diminished in cases of preeclampsia and eclampsia. It may be that the constriction of the small blood vessels alters the vessel wall sufficiently to aid in the production of edema. On the other hand, one must consider that the lack of excretion or removal of certain metabolites and steroids is concerned with the production of edema.

Also, there must be sufficient concentration of the serum proteins in the blood stream to prevent the fluid from becoming extravascular. With this in mind, we determined the number of red blood cells, the amount of hemoglobin and the total proteins in the plasma of 200 Negro women and 100 white women. All patients were pregnant. The average determinations were within normal limits and were not significant in those patients with toxemia of late pregnancy. However, in 2 eclamptic patients with total serum proteins of less than 4 Gm. per hundred cubic centimeters of blood, the administration of large volumes of plasma, totaling in each instance more than 2,000 cc., resulted in recovery of the patient. When the total serum proteins are decidedly deficient the patient may be benefited by attempts to restore the proteins to normal levels.



Electroencephalographic tracings taken in eclamptic convulsions and recovery (compare with table 4).

If the cold pressor test is applied to a patient with a moderate degree of preeclampsia the results are significant. With the patient's hand and forearm in ice water and the blood pressure recordings being taken on the opposite arm, the blood pressure rises to an alarming degree. Albumin in the urine may increase, and the patient may even have a convulsion. It is clear that the exciting cause of the elevation in blood pressure is not the constriction of the arterioles in the arm but the spread of this constriction by means of the sympathetic nervous system until angiospasm becomes generalized. One immediately wonders whether this formula could be reversible. Angiospasm in this disease seems certain and is compatible with the physiologic explanation of its causation, which was suggested by Hofbauer.[3]

ELECTROENCEPHALOGRAPHIC STUDIES

Although intracranial pressure must be considered a factor in the presence of appreciable edema this thesis does not explain the so-called dry type of eclampsia or, probably, that with mild or moderate edema. We thought it desirable to determine whether the immediate onset of convulsive seizures is due to angiospasm as well as to the rise in blood pressure and the decrease in the volume of urine.

TABLE 3.—*Blood Findings in Pregnant Women of the Midsouth*

	Red Blood Cell Count	Hemoglobin, Gm./100 Cc.	Plasma Protein, Gm./100 Cc.
200 unselected Negro patients			
Highest	5,580,000	14.5	8.60
Average	4,140,000	11.2	6.83
Lowest	2,500,000	8.5	5.50
23, or 11.5%, with toxemia			
Highest	5,370,000	14.5	8.60
Average	4,310,000	11.5	7.13
Lowest	3,490,000	9.2	6.00
100 unselected white patients			
Highest	5,600,000	14.5	7.60
Average	4,080,000	11.6	6.50
Lowest	2,860,000	7.8	5.50
4, or 4%, with toxemia			
Highest	4,300,000	12.4	7.40
Average	3,950,000	11.3	6.80
Lowest	3,270,000	10.5	6.40

The use of electroencephalographic tracings to detect the abnormal functioning of neurones in the cerebral cortex during the convulsive and preconvulsive stages of eclampsia as well as the evidences of improvement in cortical function in relationship to treatment was suggested by Dr. T. S. Hill, professor of psychiatry at the University of Tennessee College of Medicine.

The accompanying figure presents samples of the electroencephalographic tracings made on an eclamptic patient during a convulsion and as the patient improved coincident with, and subsequent to, the administration of a continuous caudal analgesia. These tracings were recorded and are herewith described (table 4) by Dr. Hudson Jost, director of the psychophysiological laboratories of the department of psychiatry. In comparing the abnormal tracings with the normal in the illustration, reference should be made to tracing *I* (table 4), the only essentially normal one obtained on this patient.

TABLE 4.—*Blood Pressure and Medication in Eclamptic Convulsions*

Tracing	Date	Time	Medication	Blood Pressure	Sensitivity
A	4/10/46	11:48 a. m.		170/120	SS —4
		11:55 a. m.	30 cc. metycaine hydrochloride 1.5%		
B	4/10/46	11:56 a. m.		150/120	SS
		12:05 p. m.	15 cc. metycaine hydrochloride 1.5%		
C	4/10/46	12:15 p. m.		140/ 90	SS
		12:20 p. m.	15 cc. metycaine hydrochloride 1.5%		
D	4/10/46	12:21 p. m.		150/120	SS —4
E	4/10/46	12:25 p. m.		60/ 10	SS
F	4/10/46	12:37 p. m.		100/ 55	SS
G	4/11/46			136/110	SS
H	4/17/46			108/ 64	SS
I	4/22/46			100/ 75	SS.

The tracings are given in the accompanying graphic record.

Tracings *A* through *F* are samples of recordings taken at intervals during the administration of metycaine hydrochloride from *11:48 a. m. to 12:37* p. m., April

---

[3] Hofbauer, J.: The Evolution of the Biologic Concept of the Etiology of Late Toxemia, Am. J. Obst. & Gynec. 51: 514 (April) 1946.

10, 1946. *A* was recorded during a generalized eclamptic convulsion immediately prior to the administration of metycaine hydrochloride when the blood pressure was 170 systolic and 120 diastolic. *D* is that of a tonic convulsion which appeared before the blood pressure was lowered by the caudal analgesia. The amplitude of both *A* and *D* is decreased 97 per cent in comparison to the standard sensitivity wherein 1 cm. equals 100 microvolts, as shown in the other sample tracings. The calibration for tracings *A* and *D* is given in the upper left hand corner of the figure. The standardization for the remaining tracings is shown in the lower right hand corner of the figure. *B* and *C* depict the interconvulsive pattern which is similar to the wave forms found in petit mal epilepsy. *E* shows the electroencephalographic tracing after the blood pressure had dropped to 60 systolic and 10 diastolic and the patient was comatose. *F* was obtained when the blood pressure was reestablished at 100 systolic and 55 diastolic. It will be seen that the cortical potential pattern is not completely normal, although the amplitude of the waves had decreased and their frequency had increased to produce a somewhat less abnormal pattern.

Tracings *G, H* and *I* depict samples of recordings made at intervals of one, seven and twelve days. *G* represents an electroencephalographic tracing taken on April 11, 1946, the day after delivery when the blood pressure was 136 systolic and 110 diastolic. *H* was obtained seven days later, at which time the blood pressure was 108 systolic and 64 diastolic and the electroencephalographic tracing was almost normal. The final sample, *I*, was taken twelve days following delivery, at which time the tracing was essentially normal.

TREATMENT

Prenatal care has done much to decrease the incidence of eclampsia. Its prevention by frequent prenatal visits is preferable to the best methods of treatment. One should adopt the attitude that every pregnancy is a potential cause of toxemia. With a systolic blood pressure of 135 mm. of mercury or more, the patient must be advised in regard to the intake of fluids and cautioned against the use of sodium chloride. Advice on elimination and a proper diet which includes the minerals, vitamins and first class proteins is of especial importance. A sudden increase in body weight is significant, as this is the first indication of a failure of renal function. One indisputable factor is the seriousness of a decrease in the volume of urine. In the presence of oliguria the patient's condition will deteriorate, and in the presence af anuria death is certain. Elimination by means of sweating and purging has been unsuccessful, and therefore all methods of medical management have depended for success on elimination through the kidneys regardless of the intent of the medical attendant. For example, the well known method of Stroganoff recommended the use of large amounts of morphine and chloral hydrate. As the central nervous system was depressed to the extent that respirations were definitely slowed, sufficient relaxation of angiospasm probably resulted. If the volume of urine increased the patient might recover, but if anuria persisted death ensued. The Temple treatment of Arnold and Fay suggested repeated spinal drainage and the intramuscular use of magnesium sulfate. In the presence of extensive edema cerebral edema is no doubt a factor, and therefore the treatment has been effective in some cases. The use of large doses of the barbiturates probably has the same effect of relaxing angiospasm.

Veratrum viride or its derivatives have been used in the treatment of eclampsia since the middle of the seventeenth century, and the relaxation of angiospasm is accomplished directly by the use of this drug. We have been using a modification of the combined method of treatment suggested by Dieckmann, and for an accurate description of the method one should refer to his several publications. We agree with him that at least 500 cc. of 20 per cent dextrose solution should be given intravenously, provided that cardiac insufficiency and/or pulmonary edema is not to be expected. The injection may be repeated in six to eight hours and the volume of urine determined accurately by opening a previously inserted indwelling catheter. Sedative drugs, such as a 25 per cent solution of magnesium sulfate, may be given intramuscularly or occasionally intravenously, and various barbiturate compounds, preferably phenobarbital sodium, may be given in doses of 0.3 Gm. intramuscularly as necessary. We had long considered the use of paravertebral block to include the sympathetic nerves to the region of the kidneys but did not carry out this procedure. On 6 eclamptic patients we relieved angiospasm by means of continuous caudal analgesia administered by Dr. Robert A. Hingson. The number is so small that the fact that all survived is not significant. However, after the block was established to include the kidney level and with the aid of hypertonic dextrose solution diuresis was established, which in our opinion was on the basis of the relaxation of angiospasm.

The word toxin in regard to the toxemias of late pregnancy will probably in time be supplanted by the word hormone. The observations of various investigators are now at such variance that a review is only confusing. It is probable that the placenta does not produce a toxin but rather stimulates the production of pressor substances which are not sufficiently destroyed by the liver. Therefore the factor of nutrition enters into the problem and is in agreement with the fact that our patients are usually the indigent and the malnourished.

Although the incidence of eclampsia was reduced during the starvation period after World War I, and this situation will probably be found in regard to World War II, nevertheless pregnant women were obtaining sufficient protective substances in their decreased diets. The deficient diets of both groups reported are similar. The Chinese poor eat rice, millet and koa-liang, a kind of corn. The poor of the Midsouth eat cornbread, salt fat pork and various types of beans. It is clear that the first class proteins, vitamins and, to some extent, essential minerals are deficient in the diets of the two groups.

In considering eclampsia one of the first questions is "Where do we see eclamptic patients?" Regardless of the geographic location it is clear that for the most part we see them on the charity services of the hospitals. This was apparent from our observations in the Philippines (1942-1943) where, at the Philippine General Hospital, we saw a large number of eclamptic patients; they too were among the indigent group.

COMMENTS AND SUMMARY

Study of the data contained in this report brought out several factors. Race did not seem to be significant. There was no appreciable difference in the two groups in regard to the ages and parity of the patients concerned. The stage of gestation was almost identical. The blood chemical findings are very similar, and the lower blood pressures in group 1 are in accord with the low blood pressures which are in general found among the Chinese. The high incidence of eclampsia among the Chinese is significant, and the incidence in our group in the Midsouth is unusually high. This high incidence will be reduced only when the public is better informed on the benefits of prenatal care, which includes advice in regard to a properly balanced diet during pregnancy. We must look far into the future before being able to report such a small incidence of eclampsia, namely, 0.018 per cent, as was reported by Davis and Gready[4] of the Chicago Lying-In Hospital. Our mortality rate among eclamptic patients in either Peiping, China, or Memphis, Tenn., does not compare favorably with that reported by others. In the reduction of this mortality not only is an appreciation of the value of prenatal care essential but also it would be wise to adopt uniformly a review committee to investigate all maternal deaths, as was done in 1934 in Philadelphia and reported by Williams.[5]

Our figures on the red blood cell counts and hemoglobin determinations are somewhat lower than those commonly reported. In the toxemic group they are difficult to evaluate because of the blood dilution of pregnancy and the blood concentration associated with the toxemias. Total plasma protein determinations were not significant except when appreciably lowered.

Rosenbaum and Maltby[6] have suggested that an electroencephalogram might be used to predict the development of eclampsia in patients. We had long hoped to demonstrate that the immediate cause of the convulsions of eclampsia is or may be angiospasm. Electroencephalographic tracings were made on 6 eclamptic patients during convulsions. All the tracings are similar, but those used in this report were more clearcut. It is significant that an eclamptic patient treated with veratrum viride gave the same type of tracing. One might contend that the alteration in the tracings is the result of the fall in blood pressure, and this is probably correct, for the fall in blood pressure is due to the relief of angiospasm whether by the use of regional nerve blocking or by the action of a drug, such as veratrum viride. We are not experts in the use of the electroencephalograph but are willing to accept the advice and interpretation of those who are. It is the opinion of Drs. Hill and Jost that these tracings demonstrate anoxemia of the brain which we consider to be due to angiospasm. However, it is clear that in the presence of extensive edema other factors require consideration. It seems reasonable to conclude that angiospasm is probably both the immediate basis for the syndrome of eclampsia, accounting for the gradual or sudden rises in the blood pressure and the suppression of urinary excretion, and the exciting cause of the convulsive seizures in some patients. The placenta is probably the stimulating factor in the patient's production of pressor substances. Methods of medical management rely for their success on the relaxation of anginospasm directly or indirectly.

ABSTRACT OF DISCUSSION

Dr. Robert N. Rutherford, Seattle: I enjoyed Dr. Whitacre's paper a great deal because he presented two series of cases from diametrically opposed racial groups of the same general sociologic level, and yet the figures from both China and Tennessee could be interchanged without significant alteration. The potential value of the electroencephalogram as an agent in predicting which patients with impending preeclampsia may go on to a more serious clinical state is an interesting observation. The investigative work which has been done suggests that malignant angiospasm or malignant vasospasm is the cause. An analogy might be drawn between the malignant angiospasm of the eclamptic state and arteriosclerosis. If the angiospasm is maximal in the cerebral circulation, there is toxemia with convulsions (in arteriosclerosis, a cerebral accident). If it hits largely in the kidney, the anuria-oliguria problem must be combated, with its final stage the cortical necrosis of the kidneys. And all physicians are aware of toxic separation of the placenta, in which the emphasis is placed on the uterine circulation; angiospasm has done its worst damage there. If this is accepted as the concept of deranged physiology, the cause is still unknown. Logically it would concern the placenta, since that is the only new endocrine organ introduced into the pregnant body and it is removed at the end of pregnancy. The line of investigation most attractive to the discussant is the work on acetylcholine esterase, the enzyme produced for the destruction of acetylcholine by the placenta as by other tissues of the body. If an imbalance exists, the angiospasm is possibly due to an overemphasis of the influence of the sympathetic nervous system on the cardiovascular-renal system. Hence, the abnormal endocrine pattern, the disordered laboratory findings and the confused clinical pictures spring from this imbalance which is caused by abnormal production of this enzyme by the placenta. The latest weapons for application in this eclamptogenic syndrome aim at releasing the malignant vasospasm. First is veratrum viride, which gives increased parasympathetic effects: it is an old drug whose use has been revived with a better understanding of its physiologic application. The other is the use of continuous caudal or spinal anesthesia in a variety of ways which temporarily relieve the angiospasm.

Dr. R. Luikart, Omaha: Since the advent of sulfonamide drugs and penicillin chemotherapy many of the obstetric complications due to infection have almost disappeared. Toxemia of pregnancy has become the number one enemy. Dr. Whitacre put his greatest emphasis on the study of eclampsia per se but said little of prophylaxis. The high mortality in such cases as here reported, which have been so well managed, makes one realize that prevention necessarily is the treatment of choice. A series of more than 1,000 obstetric patients who were organically sound and of normal weight reached term without the development of toxemia in 1 patient, i. e., no systolic blood pressures above 140 or diastolic above 85 and no appreciable albuminuria or retention of fluid. This was accomplished by holding the patient's gain in weight to not more than 2 pounds (0.9 Kg.) in any one month. The diet was high in protein, mineral and vitamins (the blood-making and baby-building foods). The amounts of carbohydrates and fats in the diet were restricted in accordance with the patient's gain in weight. The results in this series were so gratifying that in my opinion a selected diet, proper ingredients and amounts along with good hygienic prenatal care will go far to reduce eclampsia and obstetric deaths.

Dr. Frank E. Whitacre, Memphis, Tenn.: In regard to Dr. Rutherford's discussion about the cause of eclampsia as related to the placenta, it seems to me that the placenta is in all probability the stimulating factor—not that it produces any toxin. It is very probable that the word toxin will in time be replaced by the word hormone, but at present the results of the work of the numerous investigators are at such variance that to review them would only be confusing. I want to thank Dr. Luikart also. Prophylaxis, of course, is the *only* means of effectively treating disease. The attack on eclampsia will be carried out in the same way as the attack on other disease entities; it must be made by combat teams of the men skilled in basic science working in conjunction with the clinicians.

CONCEPTS DERIVED FROM INVESTIGATIONS PERTAINING TO HIGH ALTITUDE FLIGHT

CAPTAIN A. R. BEHNKE (MC), U. S. NAVY
Bethesda, Md.

In the early days of aviation, just preceding World War II, it became apparent that the structural, biomechanical, psychologic, physiologic and chemical descriptions of man were scarcely more than fragmentary when he was considered in relation to the problems inherent to his most recently created environment. Of necessity considerable progress was made during the war in adding to these descriptions. Increased knowledge has afforded him at least partial protection against the formidable stresses of flight. In many cases expedient or makeshift devices based on none too well established conclusions have been employed in his behalf. Nevertheless, at the end of the war man was flying at speeds of about 500 miles per hour and at altitudes approximately 8 miles above the earth.

The problems in aviation medicine are becoming even more numerous and more difficult in this postwar era, in which man, in flight, is pursuing and will soon be outdistancing sound itself. The chief medical problem, protection against high accelerative forces, suggests the difficulties confronting the physiologist in altering, for example, a homeostatic circulatory arrangement that evolved in an environment of relatively slow motion. The aviation engineer of necessity must now adapt his design to conform with the tolerances and the capabilities of the man.

TABLE 1.—*Average Pulse Rate Response to Exercise* of Forty Men on Two Occasions (Interval of Five Days)*[4]

	Standing Pulse Rate		Pulse Rate 5 to 20 Seconds After Exercise		Pulse Rate 105 to 135 Seconds After Exercise	
Date	June 7	June 12	June 7	June 12	June 7	June 12
Range ..	64-116	64 116	23 39	23 39	32 58	29 57
Mean	92	88	33	32	44 6	42
Median	92	88	33	31	43	41
Interquartile range †	80 104	80 96	30 36	28-35	41-49	35 49

* Twenty step ups in thirty seconds on a platform 18 inches high, the same leg being used, timed with a metronome.

† Tenth and thirtieth pulse rate values (25 per cent above and below median), when these values are averaged in order of increasing magnitude.

It is my purpose in this paper to enumerate some of the concepts and conclusions derived from extended research programs of the National Research Council, the Army and the Navy which are of interest to doctors of medicine and to mention some of the investigations currently under way which may have significant medical implications.

SELECTION TESTS AND EVALUATION OF PERFORMANCE

The exemplary accomplishments in administration, selection and training have made possible the expansion in army and naval aviation medicine and the preparation of as many as 50,000 army men monthly for combat duty. The psychologist has played a significant role in these achievements. In applying the same effective principles underlying the medical history he has replaced intuitive methods for selection of aviation candidates by a predictive procedure employing biographic information in a statistically exact arrangement. Thus in an analysis of 8,615 records it was found that the men who scored A on the inventory had a failure rate of only 11 per cent, while those who scored E had a failure rate of 59 per cent.[1]

For evaluation of combat performance, Capt. J. G. Jenkins, H(S), U.S.N.R., introduced a novel "nominating technic." Each pilot interviewed was requested to submit the names of four pilots, two with whom he would like to fly in combat and two with whom he would not like to fly in combat. The respondents indicated the reasons for their selections. This procedure allowed for various comparisons with the ratings obtained from preflight training selection tests. The significant correlation between physical fitness and combat performance[2] is of special interest. Physical training records of 1,354 men were analyzed, of whom 707 had been chosen one or more times for the "low" combat group and 647 one or more times for the "high" combat group. The results indicated that the more desirable combat naval aviators in World War II (as nominated by their fellow pilots) tended to be taller, stronger and more athletically inclined and physically fit than were the less desirable aviators. Further, the more desirable combat aviators did significantly better in the physical training phases of the preflight program than did the men less desired as partners in combat.

Physical fitness tests as embodied in the Army Air Forces' battery and the step-up test[3] and its modifications have been of value chiefly for group comparisons (table 1)[4] or for an individual if a pattern of responses has been established. The importance of the age factor of course has been demonstrated in all military operations calling for endurance, agility and quickness of response. It is observed also in a quantitative manner as a sharp decline of endurance muscular performance with age in homogeneous groups of men 18 to 30 years of age who have engaged in the same physical training program.[5]

Pulse rate response to moderate exercise of only thirty seconds' duration, as in a step-up test, would appear to have wide application not only in the services but in routine industrial medical examinations, especially in those instances in which exposure to toxic substances may occur. An unusual shift of the mean group value after a "normal" curve had been established (fig. 1)

would serve to call attention to deleterious environmental factors in a manner similar to that outlined by Foulger and Fleming[6] on the basis blood pressure recordings. To be of value, however, an exercise test must be carried out at the same time each day and the pulse rate must be ascertained accurately. As with any laboratory procedure, if carried out with utmost care such testing constitutes a most helpful adjunct but not an absolute criterion in evaluating fitness for muscular exercise and the degree of deviation from "normal" performance.

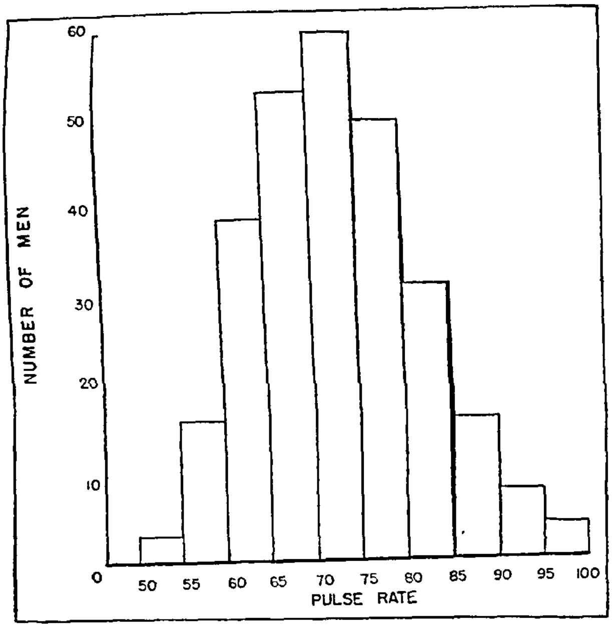

Fig. 1.—Histogram[3] showing the distribution of pulse rates obtained on a group of 281 Marines following exercise consisting of 20 step-ups to a height of 18 inches during a period of thirty seconds. The score recorded is the summation of pulse rates B + 2C, where B is the pulse rate five to twenty seconds after exercise and C is the pulse rate 120"-135" post exercise.

BODY COMPOSITION

Height-weight tables fail to provide accurate estimates of the amount of fat in a given individual. This estimate is of importance in military medicine, as obese persons are more susceptible to decompression sickness following both ascent to high altitudes and from diving depths. It also may be of value in describing overall fitness. From determinations of body density, employing a method of hydrostatic weighing based on the Archimedes principle of volume determination by water displacement, it appears that the specific gravity of the body varies inversely with, and is chiefly affected by, the amount of fat present.[7]

The concept that the body consists of a lean mass of constant composition and that accumulated fat is the major component responsible for alterations in specific gravity has been further strengthened by the quantitative studies of Rathbun and Pace.[8] These investigators obtained the same range of values, 1.021 to 1.097 in adult guinea pigs, as has been found for man. Aliquot fat-free samples of pulverized body tissue, including bone, yielded a value of 1.098. The inverse relationship, moreover, postulated for man as existing between specific gravity and fat content, has been established for the guinea pig (fig. 2).

The concept that the lean body mass is of uniform composition in mammalian species is further supported by the small variation in the percentages by weight of water and of combined nitrogen in aliquot samples of pulverized, fat-free tissue (fig. 3).[9]

ASCENT TO HIGH ALTITUDES (DECOMPRESSION)

Expansion of Abdominal Gas.—The increase in gas volume during ascent to altitude, which may be as great as fourfold at 30,000 feet, is frequently the cause of distressing abdominal pain. With the exception of certain food items, the origin of intestinal gas is swallowed air. Empirically, the following impressions are repeatedly strengthened: (*a*) Overdistention of the stomach and large bowel by expanding gas, even though slight, stops peristalsis and prevents elimination of gas, and (*b*) the amount of gas in healthy persons with good intestinal function is small and of the order of 200 cc. or less. Under conditions of semistarvation and the resultant poor physical condition together with a probably higher proportion of gas producing foods in the ration, it was found that one of three experimental chamber ascents had to be terminated because of gas pains. Further investigation should lead to an estimate of the degree of impairment of gastric and intestinal motility in relation to gas content of a viscus and should serve to test the validity of the hypothesis that effective alimentary function bears an inverse relation to gas content of abdominal viscera.

Explosive Decompression.—The engineer has been required to provide pressurized cabins in aircraft designed for great altitudes in order to prevent extreme decompression of the personnel. In such pressurized aircraft the possibility of sudden loss of pressure creates the hazard of explosive decompression, involving expansion of abdominal gases, overdistention of the lungs and even boiling of the blood and body fluids at body temperature. It has been found by German investigators that explosive decompression, irrespective of rate and magni-

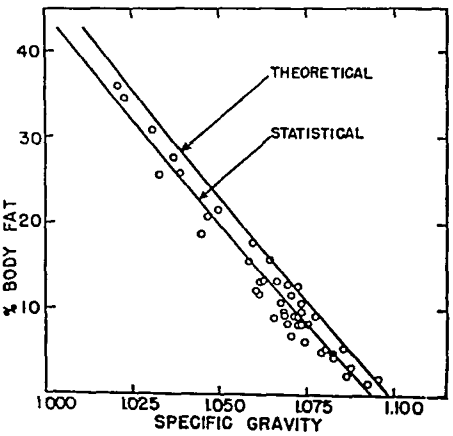

Fig. 2.—Percentage of body fat plotted against specific gravity for the guinea pig. The range of values is the same as those for man (after Rathbun and Pace[8]).

tude. does not produce injury of the lungs when the glottis is open. With the glottis closed, intrapulmonic pressures of the order of 80 mm. of mercury can overdistend the lungs and produce the type of air embolism seen in submarine escape experiments with the Momsen "lung."[10] The fundamental requisite to the production of pulmonary injury is the building up of intrapulmonic pressure to a level (about 50 to 80 mm. of mercury) where alveolar vessels rupture and air is aspirated into the circulation during succeeding respirations. Protection against rapid gas expansion or boiling of the blood can be afforded by suitable application of counterpressure or by precluding the possibility of increase in volume of the body.

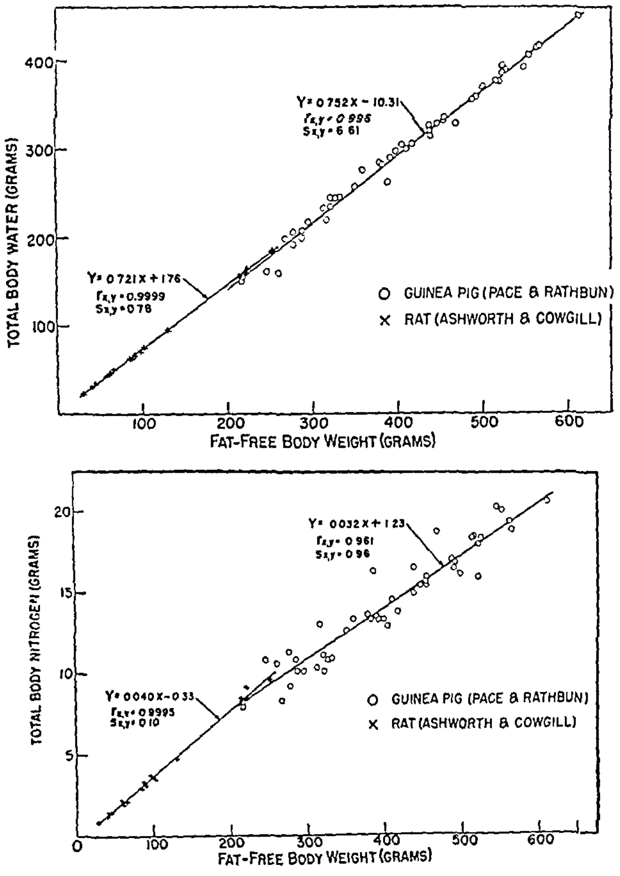

Fig. 3.—Upper graph represents total body water plotted against the fat-free body weight for each animal in our series of guinea pigs and for each animal in the series of rats studied by Ashworth and Cowgill.[9] Lower graph represents total body nitrogen plotted on the same basis. The equations were obtained by the method of least squares.[8]

Pneumothorax.—During rapid decompression spontaneous pneumothorax may arise from the overdistended lung. Gersh[11] found that when cats were rapidly decompressed gas frequently reached the mediastinum and thoracic space by dissection between visceral pleura and alveolar tissue.

Treatment of Aero-Otitis Media.—About 25 per cent of personnel in submarines and aviation will show some degree of pressure trauma in the middle ear as the result of rapid alteration (compression usually) of barometric pressure. The incidence of "ear block" sufficient to prevent rapid accommodation to compression in chamber tests usually is considerably less but may vary from 5 to 20 per cent in individuals exposed. Treatment of the chronic type of this refractory and distressing ailment was only temporarily palliative prior to the introduction of radium applications to the tubal orifices by Crowe and Baylor[12] and Crowe and Burnam.[13] This type of treatment constitutes a major advance in preventing the most common difficulty in adjusting to pressure change.[14]

Decompression Sickness.—The incidence of decompression sickness is related to the conditions underlying gas bubble formation, which fall into two groups.[15] In the first are those conditions which tend to increase the free or dissolved gas content of tissues, namely the amount of fat, the degree and duration of exposure to pressure (diving) and, following rapid ascent to high altitudes, exercise, which serves to introduce carbon dioxide into the circulation. In the second group are variables such as age, time of day, temperature, fright, injury of tissue and the postalcoholic state, which affect the circulation of blood and the transport of gas from tissues. The factor of age in the sense that the 20 year old group is less susceptible to bends than a group seven or even five years older applies even to carefully preselected men who have passed stringent physical examinations. The results of thousands of low pressure chamber runs at various aviation training centers emphasize the significance of the age factor.

This second group of factors which is associated with circulatory and vasomotor phenomena appears to affect "effective blood flow" through tissue. An appreciation of the meaning of effective blood flow through tissues is derived from curves showing gas absorption prior to and following reactive hyperemia[7] and from a comparison of the tolerance of various animal species to rapid decompression following saturation exposures at high atmospheric pressures. Man tolerates a sudden drop in pressure of 2 atmospheres to 1, the dog and cat about 4 to 1, the guinea pig 5 to 1 and the mouse 6 to 1. The tolerance of various species for rapid decompression approximates values for basal metabolic rate per unit of body weight. Even in the same species (man), bearing in mind the importance of the age factor, one would expect a fair correlation between basal metabolism and bends susceptibility in the resting state.

The symptoms of decompression sickness observed at high altitudes and those following deep sea diving are similar with one exception: the spinal cord, in some remarkable manner, escapes injury in the low pressure chamber. The importance of the factor of exercise in precipitating bends at decreased pressure appears to be related to an enlargement in size of small bubbles, which otherwise might be innocuous, by an increased formation of carbon dioxide.

"Chokes" occurring at high altitude and the development of a state of shock undoubtedly have the same cause (intravascular bubble formation) as similar symptoms following decompression from high pressures.

Recapitulation of some experimental and empirical data tends to clarify the problem. Dogs, monkeys and cats can be prepared so that bubbles following decompression from high pressure atmospheres are seen to circulate in arteries and veins until their accumulated size brings about a cessation of blood movement. With the first appearance of bubbles in the blood stream,[15] respiratory rate increases and in the anesthetized dog may develop into a tachypnea of 100 respirations per minute. Blood pressure rises slightly and then falls, and pulse rate decreases (fig. 4). Arterial oxygen saturation may be reduced to one fourth, arterial carbon dioxide content increases and the arterial-venous oxygen saturation difference may be increased fourfold. The picture is that of acute asphyxia, interference with pulmonary gaseous exchange and a slowing of circulation. Varying degrees of hemoconcentration follow, depending on the degree of vascular injury produced by the asphyxia. Recovery follows restoration of circulation by recompression (fig. 4), which removes the obstructing bubbles.

In man "chokes" apparently do not develop until rather large quantities of gas have moved from the peripheral circulation into the large veins, the right side of the heart and the pulmonary vessels. The earliest sign of "chokes" is a sensation of substernal distress, felt only during deep inspiration, which frequently elicits the cough reflex. This sign has proved most useful. Dr. A. C. Ivy [16] has compared this distress with that produced by vigorous exercise prior to the development of "second wind." The sensation of substernal distress may only be transient or it may progress to frank asphyxia. Normal breathing becomes rapid, shallow and then dyspneic. The skin becomes cyanotic or ashen gray, cold and clammy. The pulse beat, at first slow and pounding, becomes thready. Paroxysmal attacks of coughing, or true "chokes," may precede loss of consciousness. The picture is one of "shock" and represents a transformation within a period usually of several hours from a state of health to one of incapacitation by an agent obstructing circulation of blood without evidence of external trauma underlying its cause. Recompression restores blood flow by removal of emboli. The transformation from the shocklike state approaching death to a condition followed by complete recovery is another example of the tremendous recuperative power of man.

The symptomatology of decompression sickness is attributed by some clinicians entirely to extravascular bubbles. This conclusion may be due in part to a faulty interpretation of x-rays; small intravascular bubbles may, as Gersh [17] has shown, appear as streaks along fascial planes. The rapid, shallow breathing (tachypnea) which does not produce substernal distress unless voluntary deep inspirations are made could be ascribed to reflex stimuli initiated by the intermittent distention of gas filled blood vessels in response to the pulmonary pressure changes accompanying respiration. The production of pain by distention of blood vessels, however, has not been demonstrated. Another possible explanation is that interference with blood supply to tissues may be responsible for the pain of "bends" and "chokes." Other hypotheses less well supported relate the cause of pain in "bends" to the presence of gas and a possible dissecting action in nerve sheaths (gas bubbles can form in myelin), in fascial planes and under the insertion of tendons. It is certain that gas can exist in and around fat cells and in joint and tissue spaces even as extensive aeroemphysema without causing pain. Furthermore, there are no pathologic changes in decompression sickness apart from destruction of fat cells that cannot be accounted for on the basis of ischemia and the presence of intravascular bubbles.

ANOXIA AND RESPIRATION

The development by Cournand and his co-workers [18] of technics to obtain blood from within the chest and even the abdomen of human beings by means of catheters and the pressure measurements possible have given great impetus to the acquisition of quantitative data to settle longstanding controversies in the field of respiration.

Diffusion Respiration.—At high simulated altitudes (47,000 feet) useful consciousness can be maintained for periods of at least three hours by increasing intrapulmonic pressures 8 to 12 inches of water above ambient pressure during an intermittent or continuous type of pressure breathing. Pressure breathing, however, involves some degree of hyperventilation with a resultant loss of carbon dioxide. The principle to be emphasized is that if the lungs are filled with pure oxygen diffusion alone will keep the blood oxygenated: respiratory movements are not essential for this purpose. At high oxygen pressures [19] and at atmospheric pressure [20] this principle has been verified. At high altitudes, however, it has not been exploited, particularly under conditions in which undue loss of carbon dioxide was not desirable.

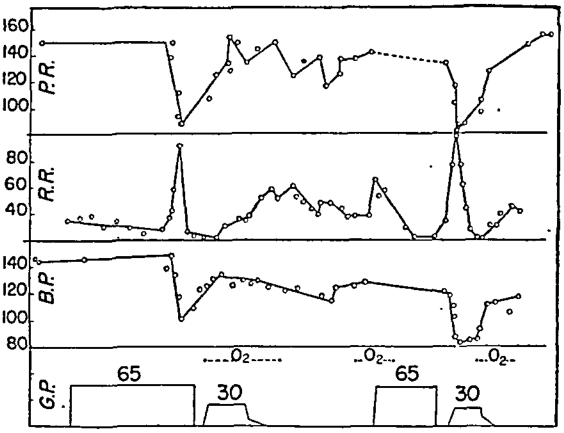

Fig. 4.—Alterations in blood pressure, respiratory rate and pulse rate of a dog decompressed in ten seconds from a gage pressure of 65 pounds after exposure of an hour and a half followed by recompression (interval of ten minutes) to a pressure of 30 pounds (oxygen) for twenty-five minutes. Pressure was then lowered to atmospheric in twelve minutes, and oxygen inhalation continued for seventeen minutes. Preceded by a period of oxygen breathing (thirty minutes), compression of the dog was again carried out at a pressure of 65 pounds for a period of forty-five minutes followed by a ten second decompression. After an interval of twelve minutes the dog was recompressed to a pressure of 30 pounds for twenty minutes (oxygen inhalation).[15]

[20] Draper, W. B., and Whitehead, R. W.: Diffusion Respiration in Dog Anesthetized by Pentothal Sodium, Anesthesiology 5: 262-273 (May) 1944.

Pulmonary Ventilation in Relation to Anoxia.—Although increased pulmonary ventilation has long been recognized as the chief compensatory response tending to counteract anoxia when air is inhaled, there has been failure generally to control breathing during the performance of tests and to estimate altitude tolerance.

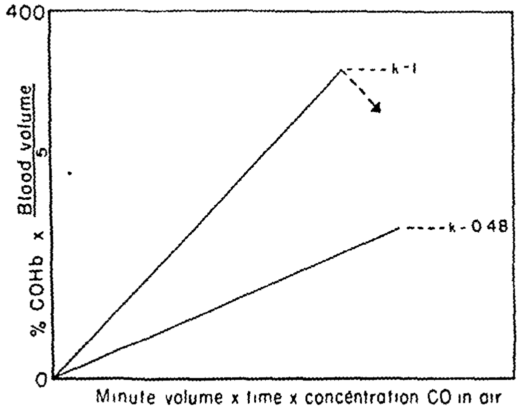

Fig 5.—Amount of carbon monoxide taken up by the blood plotted against the quantity of carbon monoxide inhaled. The slope of the line is governed by the fraction of carbon monoxide taken out of the inhaled air. This relationship holds for a carboxyhemoglobin saturation of at least 30 per cent (about 400 cc. of carbon monoxide) $k = 0.48$ was the average value for a group of healthy men studied (after Pace and others [21]).

Arterial saturation at 18,000 feet may be the same as at 10,000 feet, owing solely to hyperventilation, as indicated by the data presented in table 2.

Pulmonary Ventilation in Relation to Carbon Monoxide Uptake.—Investigations conducted during the war on carbon monoxide uptake [21] led to an accurate description of the relationship between the variables concerned and the important role played by respiratory minute volume. Up to carbon monoxide hemoglobin saturation levels of at least 30 per cent the uptake of CO may be formulated as

$$\% \text{ COHb} = \frac{\text{Min Vol (L)} \times \text{pts CO}/1{,}000 \times t\ (\text{min}) \times k}{\dfrac{\text{Blood volume (cc)}}{5}}$$

The value of *k* is of special interest, since it represents the fraction of carbon monoxide removed from each breath of air containing carbon monoxide. In graphic form, the slope of the line (fig. 5) is proportional to the value of *k*. For healthy men this value lies between 0.4 and 0.5. In patients with cardiorespiratory disease it might prove to be of diagnostic value to determine the value of *k* under conditions in which the carbon monoxide hemoglobin could be kept within safe limits (10 per cent).

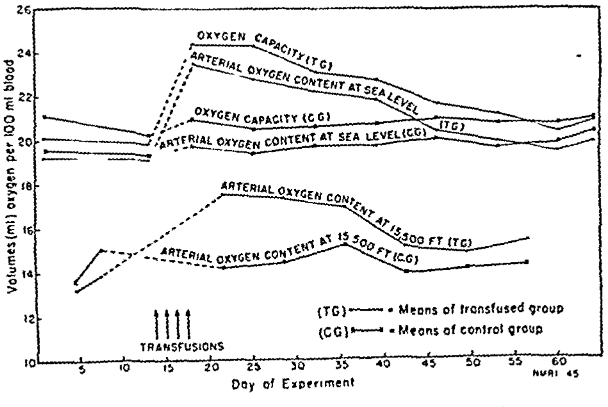

Fig. 6.—Mean blood oxygen capacity levels and arterial oxygen contents at sea level and at 15,500 feet of 10 men, 5 of whom were transfused with 2,000 cc. of a 50 per cent red cell suspension over a period of four days (transfused group) and the remaining 5 transfused with an identical volume of dextrose in saline solution (control group) over the same period [22]

Induced Polycythemia to Increase Oxygen Ceiling.—The transfusion of red blood cell suspensions into normal men appears to be the most effective method of attaining artificially the type of physiologic adaptation that takes place during natural acclimatization at high altitudes.[22] The injection of 1,000 cc. of red blood cells over a period of four days increases both oxygen capacity and content of blood (fig. 6). During the polycythemia period, which persisted about six weeks, the pulse rate following exercise when one was breathing low oxygen mixtures (at altitude) was significantly lower than control measurements (fig. 7).

ACCELERATION

Although partial protection of aviators against the effects of acceleration appears to be the chief American aviation medical research development that has contributed to superiority over the enemy, the tremendous speeds made possible by jet propulsion have created the most formidable problem in aviation. The problem resolves itself into maintaining a critical, optimal supply of blood to the brain of about 1 liter per minute under conditions that tend to cause either "blackout" (inside loop with pilot in conventional position) by reducing this supply to about one-tenth normal or "redout" (as during an outside loop) by increasing the amount several fold. Thus far, external pressure applied to the abdomen and lower extremities counteracts only one tenth of the g force that the aircraft is capable of withstanding.

TABLE 2.—*Arterial Saturation*

Normal Respiration (Min. Vol 8-10 L/m)	Arterial Saturation	Hyperventilation * (Min Vol. 16 20 L/m)
10,000 ft.	90	18,000 ft.
15,000 ft	80	22,000 ft.
18,000 ft.	*70*	*25,000 ft*

* Continuous experiment, seventy minutes at 18,000 feet, fifteen minutes at 22,000 feet and fifteen minutes at 25,000 feet (Steele, J. M.; King, B. G.; Goldman, D., and Behnke, A. R.: unpublished data, Naval Medical Research Institute, 1945)

The need to alter blood flow under the influence of high g forces by application of pressure over large areas of the body developed from the investigation begun in 1933 by Capt. J. R. Poppen (MC), U.S.N. He demonstrated by experimental flights that a great reduction in blood pressure to the head occurred under the conditions productive of "blackout" in the pioneer naval dive bombing maneuvers.

Poppen established the basic principle of circumventing splanchnic blood pooling during acceleration by means of an abdominal belt, but he was only partially successful because the lower extremities were not included in the pressurized area.

L.; Consolazio, W. V.; Pitts, G. C., and Pecora, L. J.: The Increase in Hypoxia Tolerance of Normal Men Accompanying the Polycythemia Induced by Transfusion of Erythrocytes, Project X-524, Report No. 2, Naval Medical Research Institute, May 10, 1946.

The ingenious studies at the Aero Medical Unit of the Mayo Clinic have revealed in a quantitative manner the striking increase in protection by a comparatively small increase in pressurized area in the chest region. During centrifuge runs the degree of added protection provided by immersion in water at the level of the xyphoid was 0.9 g. When the water level was raised to the level of the third rib, the degree of protection was increased to 1.7 g.[23]

In further experiments carried out by Lambert[24] the relationship of retinal ischemia (fall in ocular blood pressure) to "blackout" was demonstrated. Peripheral vision was lost when the effective systolic blood pressure to the eye (systolic pressure at the head level minus intraocular pressure) was reduced to about 20 mm. of mercury. In oxygen poisoning a similar type of functional, rapidly reversible "blackout" (loss of vision without loss of consciousness) occurs in association with derangements in blood pressure and possibly in disturbances of tissue oxidative processes and retinal circulation (fig. 8).

With reference to the development of protective anti-g suits it may be said that even after basic physiologic principles had been clearly established it required a great deal of effort and time (1941 to 1944) to provide a garment acceptable to aviators and effective in aircraft. Only through the close cooperation of army and navy officers, civilian scientists and manufacturers was it possible to incorporate scientific principles in the design and production of practical and acceptable products. The history of the anti-g suit illustrates the huge integrated effort stemming from good administration that is required to put into field operation a protective device based on rather obvious principles.

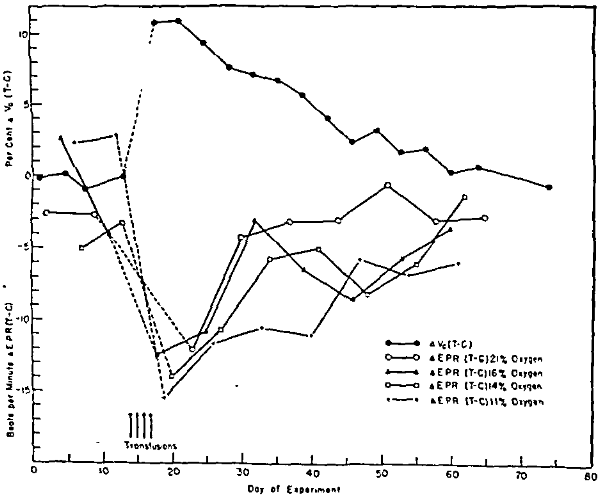

Fig. 7.—Uppermost curve (solid circles) represents the difference (ΔV_c) of hematocrit values between the transfused group (T) and the control group (C). The four lower curves represent the difference in exercise pulse rate (Δ E. P. R.) between the transfused groups (T) and the control group (C) while breathing the various mixtures of oxygen and nitrogen. The four transfusions of 500 cc. each are indicated by arrows.[22]

The approach to sonic speeds by means of the principle of jet propulsion and the possibility of human participation in rocket propulsion and its attendant supersonic speeds call for a radical extension of the range of individual protection. Protective measures must be worked out at the time the engineer formulates his plans so that they may be incorporated in the aircraft design.

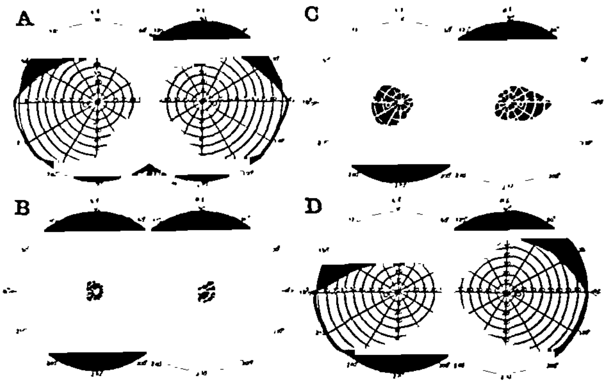

Fig. 8.—Perimetric measurements made before and after three and one-half hours' oxygen breathing at 3 atmospheres pressure (30-pound gage). *A,* normal field limits; determinations made with the Ferree-Rand perimeter and exposure method with 7 foot-candles illumination. *B, C* and *D,* field limits five, twenty-five and fifty minutes respectively, after three and one-half hours' oxygen breathing; observations made at atmospheric pressure with a black perimeter of 25 cm. radius illuminated by a blue bulb placed behind and above the observer's head; moving stick stimuli were used and checked by the exposure method; test object was a white disk 6 mm. in diameter (from Behnke, Forbes and Motley. Am. J. Physiol. **114:** 436, 1936).

PROTECTION AGAINST INJURY

Investigation of methods of protecting personnel against crash injury from impact forces constitutes a vitally important part of the research programs of the military services and the Safety Bureau of the Civil Aeronautics Board. The successful accomplishment of such studies is of value not only to aviation but to all fields of locomotion. An aircraft may be almost completely demolished and yet the human body may escape injury. On the other hand, the body may be crushed under conditions in which the fuselage is relatively intact. It also happens that in some crashes one or two of the crew will be killed while the others virtually are unharmed, as the pioneer studies of DeHaven have pointed out.

The resolution of these apparent incongruities may be accomplished by reference to two basic principles long employed by engineers to protect fine instruments against tremendous explosive forces transmitted through the steel hulls and decks of ships ("solid blast"[25]). The first is to eliminate injurious transient peak forces developed in impacts by dissipating the energy over a longer period of time. The second principle, closely integrated with the first, is to provide protective materials capable of absorbing, without recoil, part of the energy imparted by impact forces.

The type of protection devised to mitigate "solid blast" injury illustrates the first principle. Thus, if a metal loop is placed in the heel of a shoe, the compression of this loop through a distance of 1 inch may be sufficient to absorb the energy of peak acceleration and lower the impact force on the body itself to a level below the limit of tissue tolerance Tests of some of these materials can be made under conditions of static loading, although their response may not be the same under dynamic loading conditions. If a compression load of 1,000 pounds is necessary to break the tibia, for example, the protective material used must undergo deformation under a lesser static load in order to be effective.

[25] Barr, J. S.; Draeger, R. H., and Sager, W. W.: Solid Blast Personnel Injury, Mil. Surgeon 98: 1-12 (Jan.) 1946.

The body does not react as a rigid mass when subjected to impact force but behaves as an articulated system containing such shock absorbing materials as intervertebral disks, which serve to absorb the energy of impacts. Only a small part of the energy from a blow on the heels, for example, may be transmitted to the base of the skull.

In aviation the second protective principle was utilized by Bierman, Wilder and Hellems,[6] who, using undrawn nylon and covering wider and less vulnerable areas of the body in a body harness designed ultimately to protect the aviator, were able to reduce to about one-fifth the impact force that otherwise would reach the body. This nylon material stretches without recoil under draw loads well under the minimal force required to produce significant tissue injury.

Intensive studies to determine the limit of trauma to vulnerable parts of the body, the employment of protective material to absorb part of the energy of impact forces, the further elimination by "streamlined" construction of sharp corners and edges and even the incorporation of energy absorbing materials in compartment and cockpit construction give the greatest promise of reducing the high injury and mortality rates attending crashes arising from all types of mechanical locomotion. Whether, for example, safety belts will be worn in automobiles depends on the character of American temperament. Their protective value, however, is certain.

PREVENTION OF ACCIDENTS

In aviation, as in medicine, remedies are at best expedients; the principal objective always will be preventive measures by elimination of injurious factors. Perhaps the most recent achievement in aviation medicine is the fostering of the realization that the effectiveness of the machine depends on the degree to which it is designed to take advantage of the capabilities of man. Human factors have come to play a significant role in aircraft design; the expression "physiologic cockpit" (DuBois) is generally accepted. The doctors of medicine, the doctors of philosophy and other aeromedical personnel are beginning to plan their investigations with engineers at the drawing board and test their findings in experimental aircraft.

As the knowledge of the human structure, physiology and psychology is increased we shall be able to describe man adequately and list his specifications in such a way that tr ng methods and engineering design will permit maxi ploitati of his abilities. The presenting symptoms of intestinovesical fistula are nearly always those of irritation of the bladder. The urologist is therefore consulted in order to assure a correct diagnosis. It happens too often, however, that the cause of the so-called cystitis is not discovered, for the fistulous tract is not easily demonstrated and the condition is so rare that it may not be considered at the time a differential diagnosis is being made. For this reason, it is apropos occasionally to review the subject and report a series of cases.

The term intestinovesical is used because the primary cause of the fistula is more frequently found in the bowel, and it extends from there into the bladder. This term is preferable to enterovesical, for the latter has a mixed Greek and Latin derivation and the prefix "entero" is usually used to identify the small, rather than the large, bowel, whereas "intestino" signifies either.

Communications between the bowel and the bladder are by no means of recent discovery. The first case found in the literature occurred in the second century. Recent medical literature contains the report of several series of cases. Pascal[1] in 1900 collected 292 cases; since that time Kellogg[2] summarized 592; Higgins[3]

From the Departments of Urology and Proctology, College of Medical Evangelists.

Read before the Section on Urology at the Ninety-Fifth Annual Session of the American Medical Association, San Francisco, July 3, 1946.

and Peters[4] reported 40 and 21 respectively and summarized previously reported series. Pemberton[5] described 4 cases of vesicoappendical fistula, and Barnes and Hill[6] reported a series and emphasized the importance of making a correct diagnosis.

The cases reported in this communication include the 14 previously recorded by us and 17 additional ones. Incidence is about 1 in 600 patients with urologic disease. The condition is about twice as common in males as in females (table 1) and is most frequent in the sixth and seventh decades.

The commonest cause of intestinovesical fistula is diverticulitis of the bowel, and it accounts for 50 per cent of our series (table 2). An infected diverticulum situated near the bladder becomes abscessed, breaks into the bladder and produces a fistulous tract between the two cavities. Carcinoma of the rectosigmoid was encountered in 25 per cent of our cases; causes are enumerated in table 2.

The importance of making an accurate diagnosis of intestinovesical fistula is emphasized, for the condition may be easily overlooked and many patients suffer from severe intractable cystitis for months before the cause is discovered. If a careful history reveals that the patient passes gas from the bladder, the diagnosis is almost certain. Seldom is this information volunteered, and the interrogator should ask the patient specifically whether he passes gas from the bladder at the end of voiding. An affirmative answer indicates to the physician that he is almost certainly dealing with a patient who has an intestinovesical fistula. Ninety per cent of those in our series presented this symptom (table 3). The majority had frequency and burning on urination as well; however, this symptom was not so constant as pneumaturia.

TABLE 3.—*Symptoms*

Pain in rectum	3	10
Urine in stool	3	10

The most constant cystoscopic findings is an area of acute inflammation and edema in the fundus of the bladder. This is usually situated 2 or 3 cm. above the trigone; there is no edema and little inflammation elsewhere in the bladder. Occasionally the orifice of the fistula can be identified in the center of the edematous area, but it is usually obscured by the edema. When the fistula is of long standing and the acute phase has entirely disappeared, there is no edema and the fistulous orifice can be identified in a chronically inflamed bladder mucosa. There are several other diagnostic procedures which may be employed (table 4); however, none of them are reliable. Occasionally, a radiopaque solution injected into the bladder extends through the fistula and enters the colon; this occurred in only 3 out of 15 cases in which cystograms were taken. During proctoscopic examination, the appearance in the bowel of methylthionine chloride injected into the bladder or its presence in the bladder after injection into the rectum is such an irregular finding that these diagnostic methods are seldom of value. The roentgenologic finding of diverticulosis of the colon or the proctoscopic discovery of multiple diverticular orifices in the bowel, of a neoplasm in the rectosigmoid or of a localized area of edema of the intestinal mucosa is of some aid in arriving at a diagnosis. Carcinoma situated in the lower 10 inches (25 cm.) of the large bowel is more accurately diagnosed by proctoscopic examination than by barium enema, for frequently only the larger neoplasms are demonstrated by a filling defect in the roentgenogram.

The treatment of intestinovesical fistula is a separate problem in each individual case. If the patient's general condition is good and the fistula is a result of diverticulitis, a one stage repair is usually successful; if excessive inflammatory reaction and induration are present, a two stage operation is indicated. Of the 9 patients in this series on whom one stage repair was performed, 4 either suffered a recurrence or presented a second fistulous tract, which had not been recognized at the time of operation (table 5). Two of these underwent a subsequent two stage intervention. When it is difficult to complete the repair at the first operation, either a preliminary colostomy is done and the fistulous tract obliterated at the second operation or the two procedures are performed at the same sitting and the colostomy left open until the inflammatory induration has subsided and the bladder and bowel have entirely healed.

Most patients who present carcinoma of the lower part of the bowel which has caused formation of an intestinovesical fistula present too poor risks for radical operation, or the neoplasm is so extensive that it is inoperable and therefore only palliative colostomy is indicated. A notable exception is a case in this series, that of M. C., a white man aged 49, first seen in October 1935. A carcinoma of the rectosigmoid had necrosed through the bladder, creating a fistula. A one stage abdominoperineal resection of the rectum was done, a portion of the posterior part of the bladder wall removed and the left ureter transplanted into the fundus of the bladder. The patient had a somewhat stormy convalescence but is still living and shows no evidence of recurrence of the tumor nearly eleven years after operation.

It is often necessary in the treatment of intestinovesical fistula for colostomy to be maintained for several years and sometimes permanently. When colostomy is properly performed and the patient is taught how to care for it adequately, he is able to live a normal life. There is no odor or other evidence of his condition.

SUMMARY

Intestinovesical fistula, although not common, occurs often enough to require the physician to keep it in mind when making a differential diagnosis of the cause of cystitis. The two characteristic, almost diagnostic, criteria which lead to the discovery of the condition are pneumaturia and the cystoscopic appearance of a localized area of acute inflammation and edema in the fundus of the bladder. Other diagnostic procedures are useful when findings are indicative of the condition but are usually of little value. The curative surgical treatment of choice is two stage repair of the fistula by means of preliminary colostomy or colostomy at the time of repair. A summary of 31 cases is given. There were no recurrences in 6 cases in which the patients were treated by two stage repair.

1216 Wilshire Boulevard.

ABSTRACT OF DISCUSSION

Dr. John H. Morrissey, New York: In his series and tabulations, 1 in 600 cases of urologic disease is by no means a small incidence, the gravity of the condition being considered. The original contribution to this subject, that of Harrison Cripps, of London, in 1868, entitled "The Passage of Air and Feces from the Human Bladder," laid down basic principles of causation and diagnosis that are fundamentally unchanged today. Then, as today, diverticulitis of the colon was noted as the principal cause and, secondly, rectosigmoidal carcinoma. The passage of air—pneumaturia—or fecal matter through the urethra, associated with intractable cystitis, was the presenting symptom that brought the patient to the surgeon. In 1931, at the Detroit meeting of this section, I reported a series of 47 cases together with Dr. J. M. Lynch, of New York. It was my opinion then, and still is, that a two stage operation is the only procedure for the treatment of the condition—a preliminary colostomy, with adequate period of drainage and subsequent excision of the fistulous tract—regardless of the fact as to whether the bladder opening may have closed in the interval. If not excised, it will inevitably recur. Dr. Barnes's results would indicate that this is still the preferable method of surgical treatment. Another observation worthy of attention is the increased incidence of these fistulas in males. Cripps called attention to a similar disproportion of the sexes in his series of 38 cases, in only 6 of which the patients were women. This leads me to conclude that this complication, which, after all, is basically inflammatory in character, is in a measure connected with or associated with some anatomic structure peculiar to males. Similar conclusions have been reached by Sutton, Rankin and Judd, at Rochester, and Leon Herman and Baird Stuart, in Philadelphia. In my opinion, these structures are the prostate and, particularly, the postprostatic space. It is through this last area that the fistulous tract generally extends. Therefore, we should especially have this in mind in a study of unexplained cystitis in the male patient. The use of sulfonamide drugs and penicillin has changed the entire picture not *only in the early treatment of these fistulas but in their incidence.* The diagnosis of diverticulitis is today most frequently made and verified by roentgenologic examination as a clinical entity.

Dr. Robert A. Scarborough, San Francisco: The essayists have clearly demonstrated the difficulties of establishing a diagnosis of intestinovesical fistula. Information relative to the occurrence of pneumaturia is seldom volunteered by the patient, and the presence of feces in the urine was a symptom in less than 25 per cent of their cases. Frequency and burning would appear to be the dominant complaints. The difficulties of demonstrating the presence of a fistula are shown by the fact that this was possible in only 6 cases by cystoscopy, in 3 by cystogram, in 1 by barium enema, in 1 by instillation of dye into the bladder and in 1 by instillation of dye into the rectum. The authors have found that 50 per cent of their cases originated with diverticulitis of the bowel. This is consistent with the reports of Kellogg, of Higgins and of Ewell and Jackson. Their description of the rupture into the bladder of an abscess secondary to inflammation of a diverticulum suggests a fairly acute process. However, Mayo and Miller have called attention to the fact that, as a rule, onset of the development of a fistula is gradual, with burning and frequency finally developing after repeated attacks of moderate pain in the left lower quadrant. In several of their patients, symptoms referable to the bladder developed without any antecedent abdominal or intestinal symptoms. *Pelvic inflammatory disease and surgical trauma* are major causative agents which are notably lacking in the series of cases reported today. An unusual instance of traumatic origin recently encountered by Dr. James Dillon, professor of urology at Stanford University School of Medicine, was that resulting from the treatment of an inguinal hernia by injection. This resulted in an ileovesical fistula, due to the subsequent necrosis. The mortality rate from surgical intervention is usually high, with peritonitis the commonest cause of death. The authors, however, have had no deaths in 15 cases of fistula surgically corrected. In 9 cases the authors found a single stage operation feasible. However, there was a recurrence of fistula in 4 of these. In the 6 cases with colostomy before or at the time of repair, there have been no recurrences. This experience supports my own conviction that preliminary double-barreled colostomy, so constructed as to divert completely the fecal stream, is always advisable. This procedure simplifies the problem of dissection and repair by diminishing the local inflammatory reaction, decreases the risk of peritonitis and minimizes the possibility of recurrence of the fistula.

Dr. Grayson L. Carroll, St. Louis: I should like to call your attention to the method my associates and I used successfully in 2 cases of vesicointestinal fistula. Both were caused by the rupture of a diverticulitis into the bladder and were small. One caused gas to be passed through the urethra and the other gas plus feces. Methylthionine chloride injected in the rectum appeared *in the urine. An electrode was passed by* means of the cystoscope into the fistulous tract and the mucous membrane lining fulgurated away. The urethral catheter was retained in the bladder for a week. In each of these cases, we anticipated a major operation and were well pleased to have them close in this simple manner. Succinylsulfathiazole, 1 Gm. daily, and sulfathiazole, 15 grains (0.9 Gm.) every four hours, were administered during the period of hospitalization.

Dr. Roger W. Barnes, Los Angeles: We have not used fulguration of the vesical orifice of the fistula in any of these cases. We tried it a few times in vesical-vaginal fistula but without much success. It is interesting to hear Dr. Carroll's results in using this simple treatment.

ANATOMIC CONSIDERATIONS OF GASTRIC NEURECTOMY

At the February meeting of the Central Surgical Association, one of us (Walters) discussed with Dr. Edwin Miller of Chicago the problem of division of the vagus nerves in treatment of gastric and duodenal ulcers. Dr. Miller said that from dissection of approximately thirty vagus nerves he had been astonished to find great variation of distribution of these nerves in the vicinity of the diaphragm. He expressed the belief that the patterns of distribution should be assembled in groups with the idea of determining whether or not all the gastric branches of the vagus nerves or the gastric nerves could be removed successfully by transabdominal approach. He suggested that we at the Mayo Clinic might collaborate in such a study. The possibility of carrying out the study was discussed with Dr. J. W. Kernohan of the Section on Pathologic Anatomy and the work was begun with a survey of the literature, only a little of which will be recounted here, and the dissection of vagus nerves in more than a hundred cases at postmortem examination.

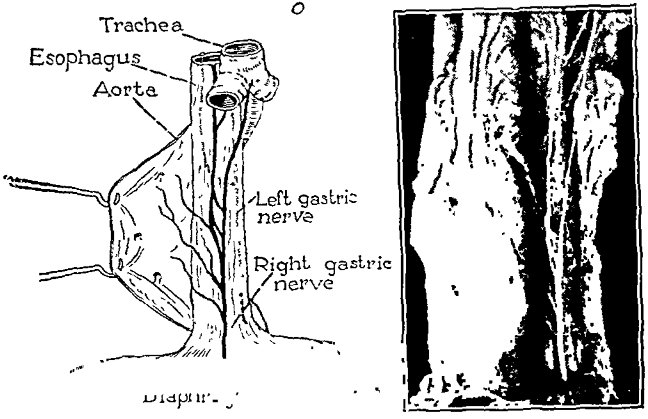

Fig. 1 *a* and *b*.—Formation of right gastric nerves from branches of the pulmonary plexus behind the trachea and sympathetic branches posteriorly. Example of group 1.

Denervation of the stomach is not a new concept in the treatment of peptic ulcer.[1] and an extensive and confusing literature has appeared since Brodie's[2] first report in 1814. A review of the literature revealed that in many instances the early and late effects of denervation have been confused,[3] and the results of section of the gastric nerves[4] of man have been compared indiscriminately with those obtained on lower animals.[5] The extent of the operation has varied in the hands of different workers, and the fact must not be overlooked that many workers have employed it in the experimental production of peptic ulcer.[5a] That there is no agreement on even the morphology of the structures of these nerves, let alone their function, is reflected in recent reports in which one author[6] concluded that the vagus nerve is composed of nothing but sympathetic fibers, whereas two other investigators[7] denied the presence of sympathetic fibers entirely. In that the present study is morphologic rather than physiologic we are concerned chiefly with clarification of the distribution of the gastric nerves[8] immediately

[4] According to Cunningham's textbook on anatomy (Waterston, David: Digestive System, in Cunningham, D. J.: Text-Book of Anatomy, ed. 7, edited by J. C. Brash and E. B. Jamieson, New York, Oxford University Press, 1937, p. 567) the vagus nerves which pass from the esophageal plexus downward on the front and back of the esophagus through the opening in the diaphragm are termed anterior and posterior gastric nerves, respectively. In our investigations the right nerve was not always posterior or the left nerve anterior to the esophagus as it passed through the esophageal hiatus and we proposed the term right gastric nerve and left gastric nerve. As any surgical procedure which would delete a section of a nerve would be known as neurectomy, when the gastric nerves are resected the procedure would be known as "gastric neurectomy."

(Footnotes 5, 6, 7 and 8 on next page)

Most patients who present carcinoma of the lower part of the bowel which has caused formation of an intestinovesical fistula present too poor risks for radical operation, or the neoplasm is so extensive that it is inoperable and therefore only palliative colostomy is indicated. A notable exception is a case in this series, that of M. C., a white man aged 49, first seen in October 1935. A carcinoma of the rectosigmoid had necrosed through the bladder, creating a fistula. A one stage abdominoperineal resection of the rectum was done, a portion of the posterior part of the bladder wall removed and the left ureter transplanted into the fundus of the bladder. The patient had a somewhat stor convalescence but is still living and shows no evi of recurrence of the tumor nearly eleven yea operation.

6 cm. above the diaphragm (fig. 1 *a* and *b*). There were 64 such cases.

In the second group there were so many intercommunicating branches between the main trunks of the gastric nerves that a plexus was formed over a major portion of the surface of the esophagus. The branches ultimately united and formed two main trunks at the esophageal hiatus (fig. 2 *a* and *b*). There were 7 such cases.

The third group was characterized by the long discrete trunks without any additions to their fibers or communicating branches for a distance of 6 cm. above the diaphragm (fig. 3 *a* and *b*). There were 21 cases of this sort.

The fourth group was made up of the remaining 8 cases. The nerves did not have a consistent or uniform course or pattern. In some instances well formed trunks were present, but somewhere near the diaphragm a well defined branch would leave the main trunk and course laterally in the thorax and lose its identity before leaving the thorax (fig. 4 *a* and *b*). In other cases the numerous branches of the esophageal plexus failed to form into common trunks on one or both sides of the esophagus (fig. 5 *a* and *b*). In such a case the multiple small fibers followed their course along the esophagus; some went through the esophageal hiatus, some ran laterally in the thorax. In such cases as these we were never quite certain of the distribution of every fiber of the right and left gastric nerves. Hence in cases of this type it might become difficult for the surgeon to section all the gastric nerves.

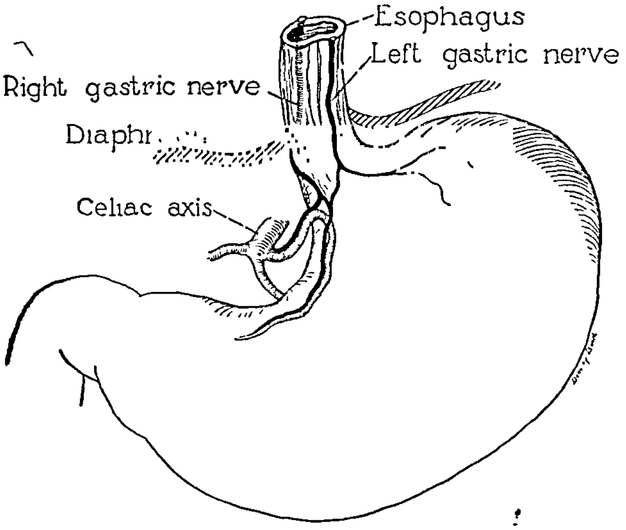

Fig. 7.—General distribution of the right and left gastric nerves below the diaphragm.

As the trunks passed through the esophageal hiatus we noted the relative position of the right and the left trunks about the esophagus (fig. 6).

Below the esophageal hiatus the course was remarkably constant (fig. 7). The right gastric nerve, the larger in 54 cases, coursed posteriorly and to the left. After about 3 to 5 cm. this right gastric nerve divided into numerous branches. One of these branches followed the lesser curvature of the stomach as far as the incisura, and another large branch followed the left gastric artery. Our routine dissections did not carry us beyond the division of the right gastric nerve into these branches.

The left nerve, on the other hand, had a short course in the abdomen. As the left gastric nerve came to lie on the anterior surface of the stomach, it almost immediately divided into numerous small branches which lost their identity in the serosa and musculature of the stomach. A branch known as the anterior nerve of the lesser curvature was consistently present behind the anterior leaf of the gastrohepatic omentum. Occasionally a small communicating branch between the right and the left gastric nerves could be identified at the esophageal hiatus.

COMMENT

This work suggests that in slightly more than 90 per cent of cases a transabdominal subdiaphragmatic surgical approach will allow of as nearly a complete division of all the gastric nerves as will a transthoracic approach. In somewhat less than 10 per cent of cases the pattern of the nerves is not uniform. In some cases numerous branches of the esophageal plexus fail to form into common trunks on one or both sides of the esophagus. In such cases the surgeon would encounter difficulty in sectioning all the gastric nerves.

AN ANATOMIC STUDY OF THE VAGUS NERVES

Influence on Choice of Surgical Approach in Patients with Chronic Peptic Ulcer

EDWIN M. MILLER, M.D.
and
CARL B. DAVIS Jr., M.D.
Chicago

The work of Dragstedt and his associates at the University of Chicago has aroused universal interest in the treatment of chronic peptic ulcer by section of the vagus nerves. Even though the elapsed time since their first operation has been only about three and one-half years, the clinical results in their series of approximately 80 cases has clearly demonstrated the value of this procedure.

We have shared the interest of many others in this work, but we were not willing to proceed with this operation before we had investigated the likelihood of anomalous distribution of the vagus nerves along the lower portion of the esophagus, the idea being that unless all the branches are divided the results of the operation might be disappointing.

We have therefore gone into the autopsy room at the Presbyterian Hospital and through the cooperation of the pathologists been permitted to make dissections of the vagus nerves below the level of the pulmonary plexus in a series of 13 fresh bodies. The textbooks of anatomy state that normally these nerves after leaving the pulmonary plexus continue as a plexus about the esophagus, from which they proceed downward as two main trunks for a distance of 4 to 6 inches, the right becoming the posterior and the left the anterior trunk as they pass through the hiatus of the diaphragm and fan out on the walls of the stomach.

From the Department of Surgery, Presbyterian Hospital, and the University of Illinois College of Medicine.

above and below the esophageal hiatus of the diaphragm. Previous investigators have shown that each gastric nerve is composed of fibers from both vagi as well as sympathetic nerves.[9]

MATERIAL STUDIED

Anatomic consideration of the nervous structures from the cardiopulmonary plexus to the stomach revealed great variation in pattern, whereas the nerves are remarkably constant in course and distribution after reaching the stomach. In dissection in more than 100 cases at necropsy we have concentrated, therefore, on the region above the stomach in order to evaluate the thoracic and abdominal approaches to the lower part of the esophagus.

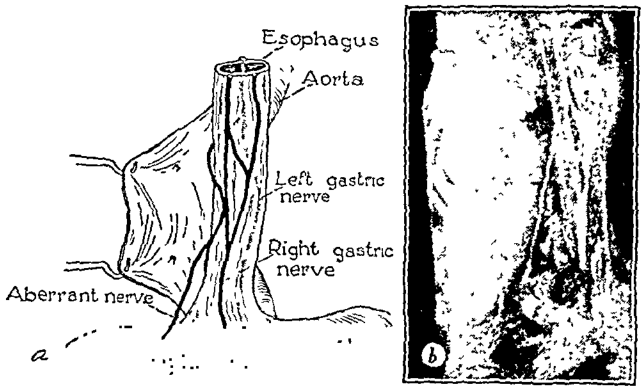

Fig. 4 *a* and *b*.—Right gastric nerve with aberrant nerve coursing laterally into thorax (group 4).

In addition to the 100 adults already mentioned in whom the anatomy of the gastric nerves was studied, we examined 11 children post mortem. Our observations in these 11 cases are not included in our results because of the difficulty in identifying the smaller twigs and branches of the nerves. As far as we could determine, however, the distribution of the gastric nerves in children is the same as in adults.

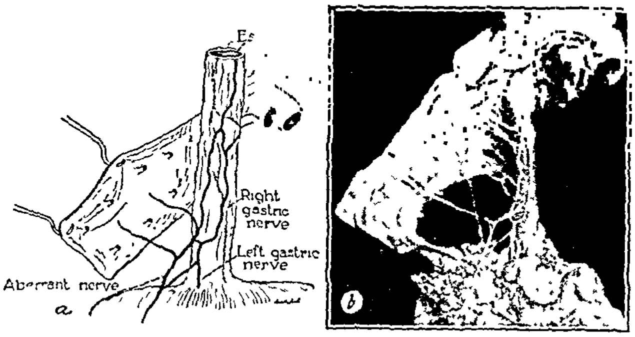

Fig. 5 *a* and *b*.—Another example of distribution of nerves (group 4).

Our observations were made on 56 men and 44 women.

Generally speaking, the gastric nerves arose from the esophageal plexus at about the level of the bifurcation of the trachea. The right and left nerves coursed caudad and usually ultimately terminated on the stomach. There were, however, certain variations that led us to separate our cases into four groups.

RESULTS

In 92 of our cases the gastric nerves took origin from the esophageal plexus. In 85 of our cases this occurred on the anterior wall of the esophagus behind the bifurcation of the trachea and behind the main bronchi. In 7 of our cases this occurred at the level of the lower part of the esophagus. As the gastric nerves coursed caudad many intercommunicating branches were observed between the right and the left trunks. Additional fibers were added to the gastric nerves by small fibers that coursed anteriorly and inferiorly over the vertebral column and the aorta. Communicating branches were sometimes seen to enter the musculature of the esophagus and either lose their identity or reemerge onto the surface of the esophagus at some more caudad position. By the time the nerve trunks and branches had reached the esophageal hiatus two relatively large trunks were formed. These trunks passed through the esophageal hiatus, below which their course was remarkably constant.

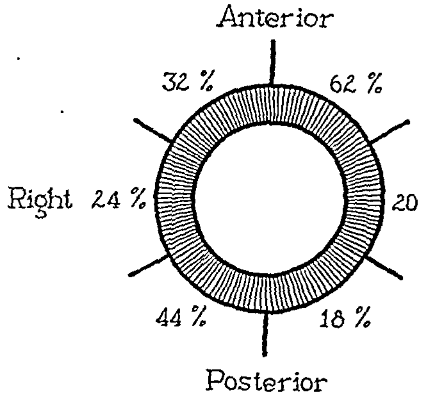

Fig. 6.—Relative position of the right and left gastric nerves about the esophagus at the level of the esophageal hiatus.

The 92 cases constitute three of our groups. In the first group all the branches between the gastric nerves and from more remote regions joined in common trunks, one on the right and one on the left side of the esophagus, somewhere between the esophageal hiatus and

AN ANATOMIC STUDY OF THE VAGUS NERVES

Influence on Choice of Surgical Approach in Patients with Chronic Peptic Ulcer

EDWIN M. MILLER, M.D.
and
CARL B. DAVIS Jr., M.D.
Chicago

The work of Dragstedt and his associates at the University of Chicago has aroused universal interest in the treatment of chronic peptic ulcer by section of the vagus nerves. Even though the elapsed time since their first operation has been only about three and one-half years, the clinical results in their series of approximately 80 cases has clearly demonstrated the value of this procedure.

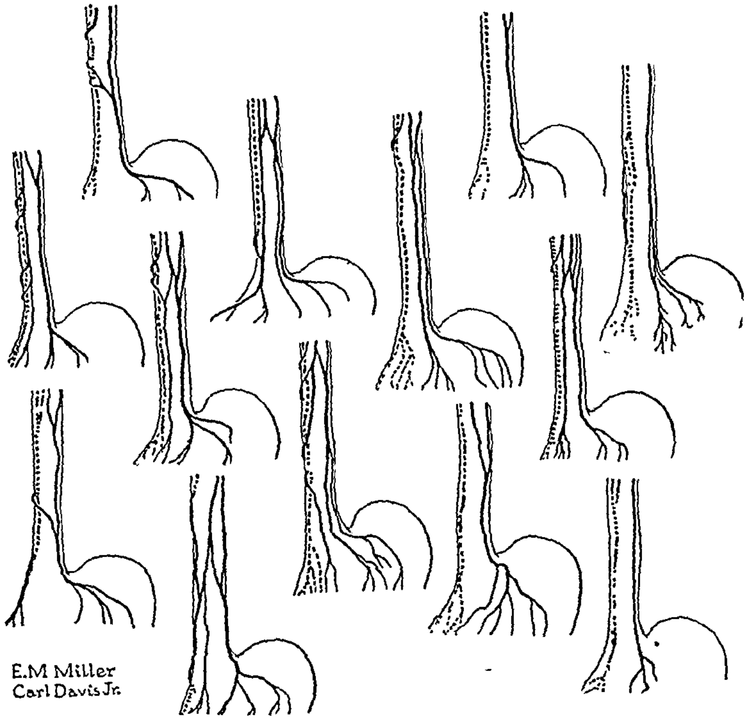
We have shared the interest of many others in this work, but we were not willing to proceed with this operation before we had investigated the likelihood of anomalous distribution of the vagus nerves along the lower portion of the esophagus, the idea being that unless all the branches are divided the results of the operation might be disappointing.

We have therefore gone into the autopsy room at the Presbyterian Hospital and through the cooperation of the pathologists been permitted to make dissections of the vagus nerves below the level of the pulmonary plexus in a series of 13 fresh bodies. The textbooks of anatomy state that normally these nerves after leaving the pulmonary plexus continue as a plexus about the esophagus, from which they proceed downward as two main trunks for a distance of 4 to 6 inches, the right becoming the posterior and the left the anterior trunk as they pass through the hiatus of the diaphragm and fan out on the walls of the stomach.

From the Department of Surgery, Presbyterian Hospital, and the University of Illinois College of Medicine.

The results of our studies have brought to light some interesting facts, as may be seen in the accompanying drawings. It will be noted that in only 3 instances was the arrangement comparable to that described in the anatomies as "normal," and in the remaining 10 bodies there was considerable variation in the number of main trunks and accessory branches.

In view of these findings we are of the opinion that in the abdominal approach with relatively poor exposure it would be a simple matter to leave undivided one or more of these branches, whereas with the transthoracic (supradiaphragmatic) approach on the left side with very careful elevation of the esophagus from its bed without bleeding (after division of the inferior pulmonary ligament) one has a clear view of this area and can more accurately make a careful dissection. We therefore strongly favor the supradiaphragmatic approach for division of the vagus nerves.



Dissection of 13 specimens at autopsy, *showing the variations in the distribution of* the vagus nerves. The posterior or right vagus nerve branches are shown by dotted lines, the anterior or left branches by continuous block lines. In only three dissections were conditions comparable to the so called "normal"

55 East Washington Street.

The Government's Research Program.—The Research and Development program of the federal government is as large as, and in many fields larger than, during the war. Current expenditures on research and development, which are at about twenty times the 1940 level, will approximate 1½ billion dollars during the year from July 1946 to July 1947, excluding expenditures on the Manhattan Project. This means not only that the federal government is conducting or financing a very large share of the total research and development now undertaken in the country but that federal policies with respect to research affect every industrial laboratory, university and individual scientist. . . . Expenditures on research related to human welfare are large in absolute terms but small in relation to all federal research and development expenditures. The Public Health Service has a budget of $11,000,000, the Department of Agriculture $37,000,000 and the Bureau of Standards $9,000,000.—Kidd, Charles V.: The Federal Government and the Shortage of Scientific Personnel, *Science*, Jan 24, 1947.

MECHANISM OF RADIATION EFFECTS AGAINST MALIGNANT TUMORS

SHIELDS WARREN, M.D.
Boston

One of the important ways of influencing growth, both normal and abnormal, is radiation. Whether applied deliberately, as for therapy of a tumor or the production, by Müller and others, of genetic effects through induced mutation or accidentally, as when epiphyseal growth of bone is arrested as a result of treating an adjacent osseous tumor, the effects of radiant energy are vividly apparent.

Whether used to end a war, as at Hiroshima and Nagasaki, or to cure a basal cell cancer of the skin, ionizing radiations act on organisms through direct production of intrinsic changes in exposed cells and through changes in the environment of the cells. The direct effects may kill, injure or induce somatic mutations in those cells that survive. Changes in morphology and growth rate are not infrequent among tumor cells which survive therapeutic radiation or among normal cells incidentally exposed and may be carried on in their descendants. Even the manner of response of the affected cells to the radiant energy may be profoundly altered, survivors among them often showing greatly increased resistance.

Since the whole basis of radiation therapy of tumors is their relative radiosensitivity as contrasted with that of corresponding normal tissues, it is well to evaluate present knowledge and to point out possible avenues for further research.

The years of observation and experimentation since the development by Roentgen of his apparatus and the recent rapid acceleration of research and development in the field of ionizing radiation incident to the utilization of nuclear energy have established for us certain basic facts.

It is the radiant energy absorbed by the tissue or cell that is effective, not that which is delivered to it. For example, a roentgen dose of 700 r generated at 180,000 volts will produce erythema of the skin, while a dose of 1,000 r generated at 1,000,000 volts is required to produce the same effect on the skin because of greater penetration and less absorption of the latter.

All types of ionizing radiations—the roentgen ray, the gamma ray, the alpha particle, the beta particle, the neutron, have essentially the same qualitative effects on cells exposed to them. It is impossible to determine by present means of study what type of ionizing radiation has produced a given change in cells. In general, tissue changes due to irradiation are characteristic, although some are difficult to distinguish from the effects of heat.

The first noticeable effect on cells is interference with mitosis—both diminution in mitotic activity and the appearance of chromosomal abnormalities. This is closely followed by vacuolization and swelling of the cytoplasm. Later pyknosis and autolysis of the injured

cells take place. Usually there is but little polymorphonuclear leukocytic infiltration of the irradiated tissue. Sometimes macrophages pick up dead cells or their fragments.

After the usual dose of radiation there is partial or complete recovery of some of the tumor cells, and were it not for the concomitant effects produced on the connective tissue stroma and blood vessels, no lasting effect on an irradiated part would be noted. Isolated cells may be extremely resistant. Over 100,000 r may be required to kill all the fibroblasts in a tissue culture.

One is accustomed to thinking of radiation as affecting a given area evenly and thoroughly. Actually, as far as the ultimate units of protoplasm are concerned, this is not the case. The following example, given by Crowther,[1] illustrates this point well: "Suppose that it were possible to pass, through the air of an ionisation chamber, X-radiation at an intensity of 1 r per second continuously, day and night, for 500 years, we should still leave about one-third of the molecules *unirradiated*."

The vascular endothelium is readily damaged, inducing thrombosis; hence local impairment of circulation in the tumor and tumor bed results. Subsequently to this there may be fibrosis and hyalinization of the vessel wall. The persisting superficial vessels in an irradiated zone usually eventually become telangiectatic.

Collagen within the field of irradiation becomes more abundant, the individual fibers first swell and then fuse, forming fairly dense hyaline, which acts as a barrier to the metabolic exchange of the tumor cells and hinders their spread into adjacent structures.

Some attempts have been made to formulate the varying response of tumors to therapeutic irradiation. The best known of these, the so-called law of Bergonié and Tribondeau, assumes that more primitive and consequently less differentiated cells are the most sensitive to damage by radiation and that well differentiated cells are relatively resistant. While this holds true to some degree, there are many exceptions to it.

By empiricism it has been possible to establish several general classes into which the various tumors may be divided in accordance with their response to irradiation. Not all tumors of a given type respond alike, but a fair degree of constancy prevails.

Those tumors that regress with a dose of irradiation that does but little harm to adjacent normal tissue may be called radiosensitive. By use of the usual size of fields and roentgen rays of moderate hardness doses ranging up to 2,500 r will cause regression of radiosensitive tumors. Among these tumors are lymphoma, angioendothelioma (Ewing) of bone and multiple myeloma.

Those tumors that regress when a dose is applied which is harmful to a moderate degree only to adjacent normal tissue are called radioresponsive. The doses in this class range from 2,500 to 5,000 r. Among these are basal cell cancers of the skin, some cancers of the thyroid and some of the cervix uteri.

Those tumors that do not regress unless given a dose of over 5,000 r are considered radioresistant. They do not respond any better than does adjacent normal tissue, which will be heavily damaged if enough dosage is given to cause regression. Malignant melanoma, carcinoma of the rectum and carcinoma of the breast fall in this group.

Radiosensitive tumors are not necessarily radiocurable. Often they are not, recurring in a resistant form after the initial regression. In addition each tumor may present individual variation in its response to irradiation, just as persons vary in their response. One of the best examples of this variation is shown by the response of a group to a slight dose of irradiation. One of the group may show no change, another may become leukopenic and still another may become leukopenic and later show leukocytosis.

Attempts to find means of selective irradiation of tumors have long been made. Most of these have been based on selective absorption by the tumor of various types of materials which would in turn absorb the roentgen rays and so enhance the effects of radiation. None have so far been successful.

In recent years the development of radioactive isotopes, first by the cyclotron and later by the pile, has opened up new fields for investigation. So far, radioactive phosphorus, which is selectively absorbed by rapidly growing cells, and radioactive iodine, which is selectively absorbed by thyroid cells under certain conditions, have been the most useful. The selective absorption of these elements makes possible to some degree irradiation of tumor cells without too much injury to normal cells.

My own experience has chiefly been with radioactive phosphorus. This is an effective means of palliation in some cases of leukemia and, if present experiments hold true, may be the method of choice in the treatment of primary polycythemia.

Radioactive iodine, which is selectively absorbed by normal, hyperplastic and, rarely, neoplastic thyroid cells, has proved to be of limited use.

Any discussion on radiation therapy would be incomplete were it to omit mention of the most potent source of radiant energy now available—the pile and atomic bomb. From Hiroshima, Nagasaki and Bikini[2] it has been learned that the biologic effects of the bombs are in large part due to the considerable amount of energy released in the form of ionizing radiations.

These ionizing radiations have much the same biologic effect as do roentgen rays, in fact some of them are identical with roentgen rays. It was learned from study of the Japanese exposed at Hiroshima and Nagasaki and from the animals exposed at Bikini that the effects of these ionizing radiations vary in general with the intensity of exposure. Those who received the heaviest radiation dosage died promptly in shock, others in whom leukopenia developed died of infection, in still others there developed hemorrhagic diathesis and in others anemia or pancytopenia. Aside from the hematopoietic and lymphoid systems, the gonads and the hair follicles were the chief organs to be damaged.

Thus the same general order of sensitivity prevails among the tissues exposed to radiation by an atomic blast as by therapeutic means.

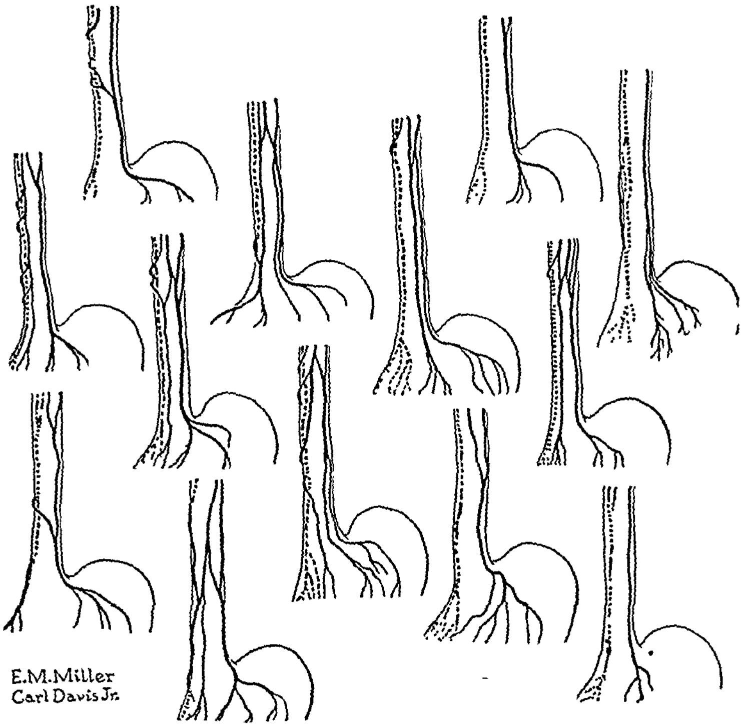
The results of our studies have brought to light some interesting facts, as may be seen in the accompanying drawings. It will be noted that in only 3 instances was the arrangement comparable to that described in the anatomies as "normal," and in the remaining 10 bodies there was considerable variation in the number of main trunks and accessory branches.

In view of these findings we are of the opinion that in the abdominal approach with relatively poor exposure it would be a simple matter to leave undivided one or more of these branches, whereas with the transthoracic (supradiaphragmatic) approach on the left side with very careful elevation of the esophagus from its bed without bleeding (after division of the inferior pulmonary ligament) one has a clear view of this area and can more accurately make a careful dissection. We therefore strongly favor the supradiaphragmatic approach for division of the vagus nerves.



Dissection of 13 specimens at autopsy, showing the variations in the distribution of the vagus nerves. The posterior or right vagus nerve branches are shown by dotted lines, the anterior or left branches by continuous block lines. In only three dissections were conditions comparable to the so-called "normal."

55 East Washington Street.

The Government's Research Program.—The Research and Development program of the federal government is as large as, and in many fields larger than, during the war. Current expenditures on research and development, which are at about twenty times the 1940 level, will approximate 1½ billion dollars during the year from July 1946 to July 1947, excluding expenditures on the Manhattan Project. This means not only that the federal government is conducting or financing a very large share of the total research and development now undertaken in the country but that federal policies with respect to research affect every industrial laboratory, university and individual scientist. . . . Expenditures on research related to human welfare are large in absolute terms but small in relation to all federal research and development expenditures. The Public Health Service has a budget of $11,000,000, the Department of Agriculture $37,000,000 and the Bureau of Standards $9,000,000.—Kidd, Charles V.: The Federal Government and the Shortage of Scientific Personnel, *Science*, Jan. 24, 1947.

MECHANISM OF RADIATION EFFECTS AGAINST MALIGNANT TUMORS

SHIELDS WARREN, M.D.
Boston

One of the important ways of influencing growth, both normal and abnormal, is radiation. Whether applied deliberately, as for therapy of a tumor or the production, by Müller and others, of genetic effects through induced mutation or accidentally, as when epiphyseal growth of bone is arrested as a result of treating an adjacent osseous tumor, the effects of radiant energy are vividly apparent.

Whether used to end a war, as at Hiroshima and Nagasaki, or to cure a basal cell cancer of the skin, ionizing radiations act on organisms through direct production of intrinsic changes in exposed cells and through changes in the environment of the cells. The direct effects may kill, injure or induce somatic mutations in those cells that survive. Changes in morphology and growth rate are not infrequent among tumor cells which survive therapeutic radiation or among normal cells incidentally exposed and may be carried on in their descendants. Even the manner of response of the affected cells to the radiant energy may be profoundly altered, survivors among them often showing greatly increased resistance.

Since the whole basis of radiation therapy of tumors is their relative radiosensitivity as contrasted with that of corresponding normal tissues, it is well to evaluate present knowledge and to point out possible avenues for further research.

The years of observation and experimentation since the development by Roentgen of his apparatus and the recent rapid acceleration of research and development in the field of ionizing radiation incident to the utilization of nuclear energy have established for us certain basic facts.

It is the radiant energy absorbed by the tissue or cell that is effective, not that which is delivered to it. For example, a roentgen dose of 700 r generated at 180,000 volts will produce erythema of the skin, while a dose of 1,000 r generated at 1,000,000 volts is required to produce the same effect on the skin because of greater penetration and less absorption of the latter.

All types of ionizing radiations—the roentgen ray, the gamma ray, the alpha particle, the beta particle, the neutron, have essentially the same qualitative effects on cells exposed to them. It is impossible to determine by present means of study what type of ionizing radiation has produced a given change in cells. In general, tissue changes due to irradiation are characteristic, although some are difficult to distinguish from the effects of heat.

The first noticeable effect on cells is interference with mitosis—both diminution in mitotic activity and the appearance of chromosomal abnormalities. This is closely followed by vacuolization and swelling of the cytoplasm. Later pyknosis and autolysis of the injured

HISTORY OF THE AMERICAN MEDICAL ASSOCIATION

MORRIS FISHBEIN, M.D.
Editor, Journal of the American Medical Association
and Hygeia, the Health Magazine
Chicago

(Continued from page 392)

(NOTE.—*Following is the fifteenth chapter of a history of the American Medical Association, in process of development for publication in connection with the celebration of the Centennial of the American Medical Association in Atlantic City in June 1947.*

The general account of the history of the Association will be followed by individual histories of the various councils, bureaus, publications and other activities of the Association. The general account is written by the editor of THE JOURNAL. *Each of the other historical contributions will be by a member of the individual council, bureau or agency responsible and now associated with it or directly related to its work. Included will be photographs, signatures and a brief biography of each of the hundred presidents of the American Medical Association. This feature has been prepared by Dr. Walter L. Bierring.*

It will be impossible to publish all of the material in THE JOURNAL. *The complete work will be published in book form. It is hoped to have it available by the time of the annual session.*—ED.)

CHAPTER 15. *The Permanent Secretary Retires and Dr. George H. Simmons Succeeds*

1895-1899

1895

BOOK REVIEWS

Book reviews have always been a source of serious discussion in medical periodicals. When publishers owned most of the medical journals in the United States a definite relationship prevailed between the character of the review, the owner of the periodical and the publisher. This abuse finally reached such proportions that THE JOURNAL found it necessary in its issue of Jan. 12, 1895, to talk about book reviews and to remind its readers that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, at least, would publish criticisms and not eulogies of new books. Some publishers had already developed the technic of avoiding distribution of books for review to periodicals which would not guarantee them favorable reviews.

Improvements in medical journals were, however, definitely on the march. In THE JOURNAL for Jan. 26, 1895 the editor announced that he would no longer publish anonymous communications, a rule that has been followed almost invariably since that date. Unless a physician cares to give his name in discussing the work of another physician or some activity of the American Medical Association, he should not wish the editor to take the responsibility for views which, in most instances, when they are to be published anonymously are venomous and hypercritical rather than honest.

Certain themes recur at cycles of five or ten years in the history of the Association. In March of 1895 the editor said:

> A certain number find great fault with THE JOURNAL, others are alarmed at what they call the *political ring rule*, and others think the Association ethics is a most serious rock of offense. . . . This is the friction that is a part of all organized movements and indicates growth and progress which is always very promising for the future.

THE FIRST FIRE

On March 31, 1895, the day being Sunday, a fire resulted in serious damage to the equipment and a flooding of the offices of THE JOURNAL. Two of the trustees and the editor arrived in an hour to find the fire practically extinguished. THE JOURNAL appeared on time, but it was quite a strain on the staff. As the year went on, the struggle for improved quality in advertising in medical periodicals began to burst more and more into the open. Letters appeared in various publications with the definite trend toward cleaning advertising pages. The committee in charge of the Rush monument was still at work and still not making much progress. A picture of Benjamin Rush was printed in May 1895, and the committee was urged to collect enough money to build this monument.

In his president's address published May 11, 1895 Dr. Donald Maclean of Detroit devoted himself largely to the history of medicine, with special emphasis on Edinburgh, where he had had his own education. He closed his address with another plea for a national department of health.

THE BALTIMORE SESSION

The annual session, held in Baltimore May 7-10, 1895, was to make history of the greatest importance for the future of medicine in the United States. The population of the United States had increased from 35,000,000 in 1866 to 70,000,000 in 1895. The population of Baltimore had increased from 250,000 to 500,000. Dr. William Osler was chairman of the committee on arrangements, and a number of interesting receptions and visits to educational institutions had been provided.

THE DRIVE FOR CLEAN ADVERTISING

The Medical Society of the State of Pennsylvania had taken the leadership in the attempt to improve the quality of advertising in medical periodicals and had brought a case before the Judicial Council against the practice. The Judicial Council discovered that the trustees and the editor had perhaps inadvertently published some objectionable advertisements. Dr. Solomon Solis-Cohen, who had assumed leadership in this movement, asked for a special committee to take up the matter with the Board of Trustees at a later hour in the session. Dr. John B. Hamilton, editor of THE JOURNAL, by a parliamentary procedure endeavored to prevent the discussion, whereupon Dr. Solis-Cohen said:

> I am speaking to the resolution. The object of this committee is to digest the report, to consider the criticisms that have been offered publicly, and to consider further what the Trustees have to say in relation thereto calmly, deliberately, without prejudice, and then report to the Association at a time when it can again be calmly discussed by the Association with all the necessary data before it. It is to prevent hasty judgment, favorable or unfavorable, that this resolution is offered. It is offered as a means of peace, as a means of carrying out the will of the Association, as a means of elevating THE JOURNAL of the Association to the proud position that it ought to occupy as the leader and not the follower of the medical press of the United States. Therefore we ask that this resolution be adopted.

After much discussion, the resolution proposed by Dr. Solis-Cohen, that a committee of three work with the trustees, was tabled. Then a new resolution introduced by Dr. E. Fletcher Ingals requesting a committee to consult with the Board of Trustees was passed following a second of the motion by Dr. Solis-Cohen. Dr. Cochran took it that the appointment of such a committee was an indictment of the Board of Trustees. A motion was then made to table the discussion and, following a call for a count, the motion was tabled by a vote of 138 to 108. But the fight was not ended! Following an interlude of discussion on improved rank for medical officers of the Navy, Dr. Leartus Connor of Detroit again introduced the subject and demanded a survey as to the proportion of the membership of the American Medical Association who prescribed secret proprietary remedies. This resolution was briskly discussed and again the question was laid on the table.

The Board of Trustees reported that the editor had been instructed to refuse advertisements of proprietary remedies which were not accompanied by a formula:

> Still further to comply with what appears to be the desire of a large number of those interested in the highest success of THE JOURNAL, the editor, with the termination of present contracts, has been instructed to accept no advertisements of medicinal preparations the proprietors of which do not give a formula containing the official or chemical name and quantity of each composing ingredient to be inserted as a part of the advertisement.

When this report was read, Dr. Solis-Cohen congratulated the trustees on the fact that the Association could "at last stand upon an honest platform." He felt that the Association should demand that every other medical journal should make its pages clean from the shame of "patent" medicines.

> On behalf of the Pennsylvania delegation, as commissioned by them officially, and unofficially on behalf of the hundreds of members who came to me, as well as of various medical societies, to express their desire that we go forward to cleanse THE JOURNAL, I move the approval of the report of the Board of Trustees.

There was great applause and the motion was carried.

And still the issue was not dead. After an interlude of discussion on the raising of the dues, Dr. A. Koenig of Pittsburgh moved a vote of confidence for the Board of Trustees. Dr. Hamilton objected to this motion. There was a lot of discussion back and forth, and finally Dr. Solis-Cohen moved that the whole new discussion be tabled and it was tabled.

AMENDMENTS TO THE BY-LAWS

Next considerable discussion arose over amendments to the Constitution and By-Laws, including a proposal to establish a new section on orthopedic surgery. Dr. N. S. Davis contended that there had been too much carelessness in proposing amendments to the Constitution and By-Laws and that there ought to be more formal proposal of such amendments.

THE INDEX MEDICUS

The *Index Medicus* was again in financial difficulties, and Dr. William Osler offered a resolution requesting members of the Association to support the *Index Medicus*.

THE BATTLE OVER THE SECRETARY

This meeting has also become noted in the history of the Association because of the action that was taken regarding the permanent secretary. There was a provision in the Constitution that the permanent secretary should remain in office until either by death, resignation or removal by a two-thirds vote of the Association a change should take place. The committee on nominations brought in the name of Frank Woodbury of Pennsylvania as secretary. Dr. E. D. Ferguson of New York pointed out that the permanent secretary was really permanent and he moved that the portion of the report pertaining to the permanent secretary be not agreed to. Dr. I. N. Quimby said that the present permanent secretary had served thirty-one years and he concluded with the following emotional appeal:

> Let the sentiment of this Association be *fiat justitia*—exact justice and mercy to every one, whether he be high or low, and let this Association sustain the present secretary, at least for the present. Let us not send him home as though he had some affliction, but let us try to make him feel happy.

This motion was about to pass when Dr. William Osler stood on his chair—the better to be heard—and made the famous speech for which he was hissed, saying bluntly:

> *Fiat justitia* for the Association is all right, but let the quality of mercy be not strained. I stand here and say plainly and honestly before Dr. Atkinson what I and many other members have said behind his back, that he is not an efficient secretary of this Association, and that we have not found him so. [Hisses, followed by applause.] You may hiss if you will, but I unhesitatingly say that no more important step in advance will be taken by the Association than when it changes its secretary. [Cries of Question! Question!]

President Maclean put the motion that the present incumbent remain in office, and it was carried by a large majority. Then Dr. I. N. Love moved that the Constitution be amended so that in the future the secretary should be elected annually.

After the vote was taken, Osler left his seat, walked up onto the platform and took Dr. Atkinson's hand and whispered to him for several minutes. Exactly what was said was not recorded, but apparently it was pleasant. However, the meeting must have had some repercussions in the Osler home. Mrs. Osler wrote in a letter to a friend on June 14:

> After you left, my mother soon departed, and she was followed by one relation and friend after another and I only had time to catch my breath and be ready for that — (you know) American Med. Asso. Our plans were changed somewhat as Dr. Osler's sister-in-law died very suddenly and we of course did not take part in any of the entertainments—and Dr. Osler recalled his dinner invitations. Dr. Donald Maclean (A. M. A. President for the year) and his wife stayed here, also Dr. and Mrs. McGuire from Richmond. I hesitate to express my opinion about the A. M. A. probably yours is the same. Thank goodness it cannot come here again while we live here. . . . Dr. Osler distinguished himself by maligning old Atkinson the secretary—I was at the meeting and frightened to death when I heard him pronounce the "secretary absolutely incompetent." It was a benefit to the Association I am told, but I fail to see it.

William B. Atkinson, the permanent secretary, was by temperament and experience really entitled to hold the position that he held for so many years, until the tempest raised by William Osler led to his final resignation. He was born in Pennsylvania in 1832 and was a graduate of the Central High School in Philadelphia and then from the Jefferson Medical College in 1853 after three years of preceptorship with Dr. Samuel McClellan. He had been a correspondent of the *New Jersey Medical and Surgical Reporter*, *New York Medical Times*, the *Nashville Medical Journal* and the *New Orleans Medical Journal* and co-editor with Dr. S. W. Butler of the *Medical and Surgical Reporter*. When Dr. S. D. Gross edited the *North American*

Medico-Chirurgical Review he became its obstetric editor. Eventually he published a book of biographies of American physicians. He had been editor of the Transactions of the American Medical Association as secretary, and also editor of the Transactions of the State Medical Society of Pennsylvania when secretary of that organization. His book of biographies called "Physicians and Surgeons of the United States," published in 1878, included the lives of 1,873 physicians, and there had been a second edition in 1880. He held many teaching positions and was the author of a book called "Hints in the Obstetric Practice" and of another called "Therapeutics of Gynecology and Obstetrics." Dr. Atkinson died in Philadelphia Nov. 23, 1909.

PROGRESS WITH THE JOURNAL

In volume 25 for 1895 the name of Dr. Ludvig Hektoen appeared for the first time as an editorial contributor. There was also the name of Dr. John Ridlon. Dr. Hektoen since 1895 has contributed a number of editorials to the columns year after year and has been especially helpful in training young men to take an interest in journalism and in editorial work.

The Journal was happy in July of 1895 because it included a double page spread in three colors illustrating pathologic appearances in endarteritis. The Journal was definitely improving in the quality of its illustrations and in the make up of its pages.

THE BATTLE OF THE MONUMENTS

The battle of the monuments was now definitely on. The American Surgical Association was behind the movement to erect a statue to Professor S. D. Gross. The monument to Benjamin Rush was still having hard sledding. Then came a movement on the part of the homeopathic group to erect a monument to Samuel Christian Friedrich Hahnemann. The Rush monument fund had now reached $3,357.39.

Interesting is a letter which appeared in The Journal for Sept. 21, 1895, stating that The Journal was now too advanced for many of its readers and that it ought to print articles of less scientific value in order to reach a doctor-reader audience. This continued to be a perennial reminder that some physicians are not quite up to others and that men in the lower brackets feel that journals ought to be edited to their levels.

Louis Pasteur, among the most famous of all the names in medicine, died of paralysis at his home in Paris Sept. 28, 1895, aged 73. The first steamer built by the United States government for its quarantine service had been named in his honor. Long before the time of his death it had been recognized that his had been among the greatest of all contributions to the advancement of medical science.

The library of the American Medical Association had been transferred to the Newberry Library of Chicago. The librarian at the Newberry Library discovered in 1895 that it did not even contain a full set of The Journal of the American Medical Association or, in fact, even one volume. It had, however, begun to accumulate some excellent incunabula and some complete sets of medical periodicals.

PARLIAMENTARY LAW

The debates in the annual sessions of the previous two years were so stormy that one member, Dr. A. C. Simonton of San Jose, Calif., in the cooling off period of 1895 wrote a long letter about parliamentary law. He referred particularly to the trustees, who apparently kept copies of Roberts' "Rules of Order" in their pockets and had to refer to them frequently in the midst of debates. Dr. Simonton was seriously interested in parliamentary law, and he felt that it was about time that the rulings in the House of Delegates of the American Medical Association be more in accord with established principles.

1896

ATLANTA

On March 14, 1896 Dr. F. E. Stewart of Detroit proposed that the members of the Association have a permanent badge. He had his own ideas for such an emblem and he invited suggestions from others.

The two year lease of the Association on the rooms at 86 Fifth Avenue terminated April 30, 1896 and it became necessary to move. The stay in the Fifth Avenue headquarters had not been happy. There had been no recovery of anything on account of the damage by fire and water. The power was always breaking down, the halls were dirty, and Dr. Hamilton could not make the owner make good on his verbal promises. A lease was therefore made with the owners of the Dental Building at 61 Market Street, so that the Association occupied the third floor in a new fireproof building. The Association purchased an electric motor so that it could run its own presses. Dr. Hamilton felt, however, that the business necessity of a permanent home for The Journal was becoming more and more urgent every year. "The bad policy of paying rent," he said, "will be apparent." Thus he urged that the Association take the necessary steps to provide a fund for the purchase of property, the payment of interest and the gradual extinguishment of its debt. "The present move," he said "should be the last move in a rented building. Next time we should go into the permanent home of the Association."

SPECIAL TRAIN TROUBLE

Later in the same month the editor of The Journal was agitated because some of the members were working independently on the railroads and he had in his responsibility the matter of the special train to Atlanta for the 1896 session. One physician in Chicago who could not get a pass to Atlanta for his wife negotiated with another railroad and tried to work out a special deal with that road. A drug firm in another city, which conducted a medical journal in Chicago, tried to get a special train for that group. This interfered somewhat with the ideas of Dr. Hamilton, and he ended his editorial snappily: "Whether The Journal ever runs another special to any of the meetings depends upon the view the members take of it."

Now comes the story of a special train which must have given Dr. Hamilton a maximum of annoyance. The train left Chicago on Sunday night, May 3, by the Big Four Road. Everybody was happy and the train pulled into Cincinnati at 9:05 that night exactly on time. The train was now turned over to the Queen and Crescent Railroad. Here Dr. Hamilton discovered that the train occupied by his group would be held in Cincinnati until another train coming from Detroit—operated under the auspices of a magazine called *Detroit Medicine* and in charge of Dr. Harold Moyer of Chicago and Dr. Whitmore of Parke, Davis & Company—could join with his group. The Detroit party had about 33 people, who started out on the Monon route and were delayed somewhere in Indiana, so that Dr. Hamilton's group was held until 11:30 at night without any supper. (It was supper in those days; dinner came in some time later.) At 11:30 at night everybody got restless and so the Queen and Crescent Railroad brought down a man—"the alleged superintendent," Dr. Hamilton calls him—"a certain Mr. Stephens," to interview the passengers. Mr. Stephens, after some argument, told Dr. Hamilton that the cars belonged to the railroad and that he would move them out of the depot when he got ready. "Arguments, persuasion and entreaties were of no avail to the all-powerful Mr. Stephens, who finally, becoming tired of the importunities, sent the train across the river to Ludlow, Ky., where they completed the allotted period of the detention and were finally joined by the delayed contingent as aforesaid." The train arrived in Chattanooga at 10:30 a. m. and finally the people got something to eat. In the nature of a vast understatement, Dr. Hamilton writes "The originators of the trouble, including the alleged Stephens, were not extremely popular with any of the members of THE JOURNAL party." He continues "A number of physicians on the train made up their minds that they had learned something in the matter of travel over certain railroads, and that when it came to advising patients going South for the winter what line to take in order to have the most comfort and humane attention, they would know how to advise them. A more unfeeling and heartless treatment of passengers has seldom been witnessed than that received at the hands of Mr. Stephens of the Queen & Crescent." Were Dr. Hamilton alive today, we would tell him about the special which left Chicago for San Francisco in 1946 and arrived fourteen hours late.

CELEBRATION OF THE SEMICENTENNIAL

At the Atlanta session, among the first of the resolutions offered was one proposing a suitable celebration of the semicentennial meeting in Philadelphia in 1897.

THE PERMANENT SECRETARY

The question of the permanent secretary continued to be agitated by Dr. I. N. Love of St. Louis, but apparently the membership were not yet ready to make a change. Dr. Love in his discussion said that the ruling that had been made at the Baltimore convention to the effect that the Constitution precluding any change in the secretaryship "paralyzed everybody, consequently proper consideration was not given to the question. I know it paralyzed me," he continued, "and I do not easily paralyze." (Laughter.) Questions elicited the fact that the Constitution was so written in 1864. There was a good deal of discussion on the matter. There was some criticism of Dr. Maclean for not having put the question at the Baltimore meeting, and he suggested that in the interest of peace he had avoided it. Then there was a call for the reading of the minutes of the Baltimore session because apparently there was some doubt as to just what was done and there was some question as to whether the minutes as printed in THE JOURNAL were actually minutes of the meeting. The question was particularly agitated by Dr. H. Bert Ellis of California. Eventually the situation was cleared by a resolution to the effect that the minutes as published in THE JOURNAL be recorded as official minutes. The secretary then arose to point out that he kept his minutes in a big book, that he wrote them out every evening before he went to sleep and that the editor published them in THE JOURNAL exactly as they were in the book. He offered to have the book available for inspection but he did not think it essential because such a book would be too cumbersome to carry around from place to place. The discussion continued until it was lost in the midst of a lot of confusion and apparently nothing further was done with it at that session.

There was still more discussion as to moving THE JOURNAL from Chicago to some place else, and Dr. Garcelon of Maine introduced a resolution calling attention to the fact that the trustees had been authorized to establish a building fund and requesting a ballot of the members of the Association indicating a place where they wished THE JOURNAL to be located permanently.

The Atlanta convention was especially notable for the quality of the entertainment, which included a Georgia barbecue, and for a beautiful address given by John Temple Graves. Typical of his discourse are these paragraphs:

> Atlanta is proud beyond expression of her brilliant galaxy of physicians. We support 200 doctors in this happy town, maintain them in the most lavish splendor and the most indolent leisure. There is nothing here for them to do. In the elixir of this incomparable air and under the blue of these cloudless skies there is never an ailment that an old woman's nostrums wouldn't cure.
>
> Our doctors here are almost without exception millionaires. They practice only on the stranger within our gates. They live in stately mansions, drive in splendid carriages and spend their time in thumping the soundest of "livers" and in feeling the steadiest pulses that ever beat in unison with the hope and progress of the healthiest and bravest city in the South.

He concluded:

> Turn your stethoscopes upon us; level your heartscopes, your brainscopes, try us with the Roentgen rays of all institutions, and you will find that Atlanta, city of conventions, abating no jot or tittle of the sincerity of any past profession, has held in her heart her last and most loving welcome for the doctors of America.

MORE SPECIAL TRAIN TROUBLE

In the same issue in which he reported the minutes of the convention Dr. Hamilton gave a final curtsy to "superintendent Stephens," who had now become Stevens. He opened up with the quotation from Shakespeare:

> But man, proud man,
> Drest in a little brief authority,
> Most ignorant of what he's most assured.
> His glassy essence, like an angry ape,
> Plays such fantastic tricks before high heaven
> As make the angels weep.

Dr. Hamilton repeated the manner in which the physicians had discussed the delay with Mr. Stevens and then he said:

> All these things were explained to the great potentate, but he refused all requests and laughed in our faces, although nearly every male passenger made a personal appeal to him. That his phenomenal brutality should hurt the Queen & Crescent railroad is apparent, and if they are sorry for it they have a plain remedy, that is to repudiate Mr. Stevens, and all his works, at the earliest possible date. It is possible that even the Queen & Crescent railroad may discover that it is not good railroad management to treat a hundred physicians and their families as a trainload of immigrants.

A PERMANENT HOME

Now began the agitation over the permanent home. The trustees had set aside $3,000 to be placed at interest as the commencement of a building fund. All members were sent ballots and requested to vote on the place of the permanent home.

The first page of volume 27 of THE JOURNAL, covering the second half of 1896, reveals the addition to the staff correspondents of several names which were eventually to play highly significant parts in the growth and development of the Association. Among them was that of Emily Cushing, who served for many, many years as an abstracter of literature, and also William Whitford, who was the official reporter until age and illness caused him to discontinue this work after 34 years.

DIPHTHERIA ANTITOXIN INTRODUCED

Diphtheria antitoxin was now exceedingly prominent as the center of interest, and the American Pediatric Society had conducted quite a modern survey as to its usefulness. The evidence was so convincing that a distinguished committee led by L. Emmett Holt gave the remedy their full support and established a routine dosage. "Antitoxin should be administered as early as possible on a clinical diagnosis, not waiting for a bacteriologic culture," they said.

READING NOTICES

By this time a considerable abuse had risen in American medical journalism which again required years for its correction; it was the so-called "reading notice." The manufacturer of proprietary remedies before signing a contract for purchase of space obtained as a concession a number of editorial notices as to the worthiness of his products. The editor of The Journal protested, but apparently the abuse was quite outside his ability to correct.

A STANDARD NOMENCLATURE

On Aug. 8, 1896 the editors called attention to the desirability of a standard nomenclature of diseases—a movement which was only to find real accomplishment over forty years later.

THE PERMANENT LOCATION

At the same time the editor published the result of the ballot on the permanent location of The Journal. Chicago led with 2,128 votes; Washington received 810; New York got only 24, and Philadelphia 48; St. Louis 22 and a good many other cities received just a few votes, including such strange locations as Elmira, N. Y., and Sedalia, Mo.

LEADERS FROM MEDICAL JOURNALISM

Medical journalism at this time occupied a strange place in American medical life. Many of the leaders in American affairs were themselves editors of publications, as, for example, Dr. I. N. Love, who was a trustee of the American Medical Association, Dr. Leartus Connor of Detroit and Dr. Harold N. Moyer, a prominent delegate. Much highly personal journalism resulted from the competition. The repartee in such house organs as Merck's *American Medico-Surgical Bulletin*, Parke, Davis & Company's *Medicine*, the *New York Medical Record*, the *New York Medical Journal* and the *Philadelphia Medical News* with the editor of the Journal of the American Medical Association makes amusing and exciting reading.

MORAL HYGIENE

The hygiene of the period was a moral hygiene more than a scientific medical hygiene. Page after page was devoted to the treatment of inebriety; there were long serial articles published by T. D. Crothers, who conducted an institution for the purpose.

The bicycle was invented about that time and became exceedingly popular. Just as soon at it achieved notice, doctors began to wonder about its medical effects. There were some interesting letters pro and con the bicycle as to what it would do as a cause of vesical and prostatic irritation and how it would react on the reproductive instinct and the sexual appetite of the female. Most of the doctors were convinced however that, regardless of what the bicycle would do to health, the bicycle had come to stay.

THE FIRST EDUCATIONAL NUMBER

The month of September 1896 was highly significant because The Journal of the American Medical Association on September 19 published the first report on the medical colleges of the United States, with a description of the Association of American Medical Colleges and the Southern Medical College Association and their requirements together with a statement concerning each school, its tuition fees, its hours of study and its officers. This was perhaps the first Educational Number. Eventually repeated publication of the facts came to be the most important single step in raising the standards of medical education in the United States. Shortly thereafter The Journal began printing descriptions of diploma mills and to print letters regarding quackery which served to open these successful campaigns.

THE RUSH MONUMENT

The Rush monument project was still doing poorly, and the matter was all the more serious because the homeopaths had raised $75,000 and were in process of building their monument in Washington.

1897

THE SEMICENTENNIAL YEAR; PHILADELPHIA

The editorial pages of The Journal early in 1897 began to reflect other editorial projects of great significance for the advancement of American medicine. One was the defense of animal experimentation, necessary because Senator Gallinger had begun the introduction of a series of appeals which were to follow year after year, designed to prevent the use of animals in the District of Columbia. The Army and Navy medical departments and the U. S. Public Health Service were compelled to oppose such measures in their own interests. The American Medical Association opposed them also because enactment of such legislation in the District might well set a pattern for the rest of the nation.

In 1947 Senator Lemke had succeeded to the Gallinger toga as champion for the antivivisectionists.

HYGIENIC ASPECTS OF SKYSCRAPERS

The Journal discussed learnedly the medical aspects of the modern skyscraper. Some tall buildings were going up; the editor was worried not only about the sanitation of these buildings but also because the buildings were built with steel cores; it seemed that the steel might rust through and the building fall down. The height seemed to offer serious thoughts also in relationship to conflagrations. "Tall buildings," said the editor, "are an experiment and it is too early to say with assurance whether the predictions of those who condemn them may be fully justified."

OSTEOPATHY APPEARS

The osteopaths began to appear prominently in various states seeking recognition in legislation. The firs editorials jeered at their predictions and compared then with Madam Mapp, a famous "bonesetter" or "shap mistress." There had been bonesetters in New Englan as early as 1696. The editor of the *New York Medica*

Record had written an editorial wondering what this new eccentricity of the West meant. To this Dr. Hamilton commented:

> The *Medical Record,* however, should not be too severely criticized for its ignorance of "osteopathy" albeit a female "osteopathist" or "bonesetters" in the days of its editor's youth created a great furor in New York City. The *Medical Record's* knowledge of either medical history or medical science is, it must, charitably be admitted, an unstable quantity. It revived [illegible] II after his encounter with the nihilist by the use [illegible] oxygen sulfate." A medical journal capable of such a chemical extravaganza can hardly be taken seriously on any subject.

By the end of May, however, the editor of The Journal of the American Medical Association began to be disturbed about an osteopathy bill in the state of Illinois, where it had passed the senate.

THE SEMICENTENNIAL MEETING

The really big news of 1897 was the celebration of the semicentennial in Philadelphia. The President was Dr. Nicholas Senn of Chicago, who had already achieved worldwide fame as a surgeon. In his address he recalled the history of the organization. Four members present at the time of its foundation were still alive—Drs. N. S. Davis of Chicago, Alfred Stillé of Philadelphia, J. B. Johnson of St. Louis and D. F. Atwater of Massachusetts. Dr. Senn recalled the progress that had been made in advancing medical education, in the scientific work of the Association, in its improvement of American medical literature and in its development of its own journal. He praised the Code of Ethics and discussed the difficulties which developed when irregular systems of medical practice were introduced in the nation. "The code has fulfilled the purposes for which it was intended and will remain a *noli me tangere* for generations to come," he said. He continued:

> I am sure that this feeling will prevail at the centennial celebration fifty years from now, and that our successors will be grateful to us for handing it down to them in an unmutilated form.

He spoke at some length concerning subscriptions to the fund for the Rush monument and urged the erection of a suitable home for the Association with a hall in which its delegates could meet, a library, a museum and other features. He closed with "a glimpse of the future," which is worthy of repetition now that fifty additional years have passed:

> *A Glimpse of the Future.*—Fifty years of steady growth has made the American Medical Association strong. It has passed the experimental stage; it has done a great deal in advancing and diffusing medical knowledge and in the prevention, alleviation and cure of disease. It is the recognized final tribunal which directs and controls all other medical societies and medical educational institutions. It is the final Court of Appeals to which the regular practitioners and the public can look with confidence for the enforcement of a pure discipline and needed protection. It is the highest postgraduate medical institution in this country which without tuition provides a course of instruction annually of a scientific and practical character, well adapted for the busy practitioner, from which every one returns with a firm determination to do more and better work. It is the great bond of fraternal union which binds and cements together the physicians and surgeons and devotees to special departments of medicine and surgery. The Association has done much for the profession and the people in the past, it can and will do more in the future. The organization is now completed and in excellent working order. We can devote in the future all of our time to scientific and practical work. The increase in membership during the last two or three years is unparalleled in the history of the Association. An awakening interest in the usefulness and prosperity of the Association is noticeable on all sides. The papers read in the sections and the discussions are becoming better from year to year. The fiftieth birthday of the Association will give a new impetus to the work and growth of the Association. It is difficult to foretell the possibilities of the second half of the first century of the existence of the Association. It is, however, safe to predict that when the first centennial celebration will be held in this city fifty years from now the membership will have increased from 9,000 to 75,000 or 100,000, and our official organ at that time will be recognized the world over as the most enterprising and best medical journal. Few, if any, who, constituting my audience today, will live to see that day to bear testimony of the proceedings, festivities and incidents commemorating the first semicentennial. The President who will then occupy this Chair and who probably at this time is laboring with his lessons in arithmetic, spelling, geography and grammar in some public school will then review the work of the Association for the first century, and may we trust from the records we shall leave behind that he may adjudge us faithful servants in the cause of science and humanity. Taking up the thread of history from this day he will chronicle inventions and discoveries of which we have now no conception. The literature of today will be as old and useless as that of fifty years ago. We have the satisfaction of having been permitted to live and labor at a time when the science and practice of medicine and surgery were undergoing a complete revolution. We are now laying the cornerstone and are slowly but surely building the foundation for rational medicine and surgery. The work of the next fifty years will no doubt contribute much toward making what has been sought for ages in vain, the rendering of medicine and surgery exact sciences. The American profession will contribute liberally toward accomplishing this object.
>
> In conclusion, let us implore Almighty God to shower the richest blessings upon the American Medical Association and the labors of all and every one of its present and future members. May it please Him who, during His earthly career, went from place to place as the Great Physician to heal the sick and maimed, through His boundless mercy and tender sympathies for suffering mankind, to so guide our lives and labors as to imitate His inspiring example in relieving suffering and in adding to the happiness of our fellowmen.

The meeting in Philadelphia opened auspiciously with an address of welcome by the mayor and by the Hon. Charles Emory Smith, ex-minister to Russia, who represented the governor of the state. Mr. Smith told the convention that the governor was "detained in Harrisburg in the artistic work of amputating gangrene legislation."

There was a magnificent list of lunches and dinners at which the medical publishers of Philadelphia, the officers of various sections and other distinguished medical organizations were hosts.

After the treasurer of the Rush monument committee made his report, a motion was introduced requesting the American Medical Association to set aside $1,000 each year until a sufficient fund could be raised to build the monument. Dr. J. A. Graham of Colorado made an address pledging the state of Colorado for $2,000, whereupon a roll call of states was made and great numbers pledged anywhere from $2,000 for the state to hundreds of dollars individually. At the end of this great rally Dr. Albert L. Gihon of the U. S. Navy, who had for so many years promoted this fund, thanked the delegates and promised the Association that he would live to see the fulfilment of this work.

The treasurer of the Association made a report indicating a total business of around $56,000 for the year, with $5,000 cash on hand.

Again the question was raised as to the permanent secretary, and Dr. I. N. Love announced that he was not pushing the question. His announcement was greeted with applause. The Association had not yet developed a businesslike method for recording its membership or collecting its dues. There was a tremendous discussion over the fact that the railroad gave half rates to political bodies, synods and Christian Endeavor units but that the best the doctors could get was a fare and a third. In the midst of this discussion it was announced that President William McKinley was about to enter the hall. The proceedings state that:

> A moment or two later President McKinley came in arm in arm with Dr. Senn, who had returned to the rear of the stage to perform the office of escort, immediately after quieting down the Association. Dr. Hare preceded Dr. Senn and President McKinley; Mayor Warwick and Governor Hastings and Dr. Pepper and the others of the party attending President McKinley came after. The Association rose and cheered heartily for a minute or two. Quiet being restored, Dr. Senn presented President McKinley, who addressed the Association.

President McKinley merely conveyed greetings and stated that he had paused to pay respectful homage to the noble profession which those present so worthily represented.

Then a brilliant and witty address was made by Governor Hastings of Pennsylvania. A few quotations follow:

> We have all seen the ideal physician, whose presence in the sick room is as welcome as the morning sunshine; his voice is a benediction, his touch an inspiration and his presence an emblem of security To him children turn, and the marks of pain are changed into the expression of love and confidence. The aged reveal to him the secrets of their lives and their hopes of the life hereafter; mothers forget their vigils of the night in loving anticipation for the restoration of their revered or dear ones, or perhaps in the contemplation of the inevitable that the pathway to the tomb shall be strewn with roses in the confidence of a Redeemer's love.
>
> The development of medicine from a layman's point of view has been greater than that of any other science during the last hundred years. There was left a hiatus for a long period of time, when medicine appeared to be nothing but an empiric art. It is very, very different now. I was speaking to you a moment ago about the erection of statues or monuments to our great philanthropists, great soldiers, etc., and allow me to say that I think it is absolutely wrong and decidedly un-American that we do not erect monuments and statues to the great masters of medical science in this country. Then too I have been puzzled at the number of new diseases you have discovered. I read in a history of the fourteenth century by Horner something about diseases of the skin, in which he said there were three diseases of the skin. One was a disease which could be cured by the use of sulfur, a second disease of the skin could be cured by the use of mercury, and the other was a disease of the skin which the devil himself could not cure.

AGAIN CLEAN ADVERTISING

The Board of Trustees reported that some attempt to regulate the advertisements had resulted in a loss of nearly $4,000 because the advertisers felt that "the continued publication of a formula gives every druggist opportunity to enter into competition with the manufacturer of such specialties." The board put up to the Association its willingness to make some change in the manner and standard of advertising. There had been an increase in the membership of the Association. The board had invested $3,000 in a first mortgage on real estate in the city of Indianapolis. Because neither the Association nor the Board of Trustees was a chartered or legal corporation, the investment had to be made in the name of one of the board as trustee for the Association. Owing to a bank failure the funds of the Association had been placed in peril. This offered difficulties because the Board of Trustees did authorize that a charter should be secured. On motion the report was accepted and the action of the board in securing incorporation was concurred in.

The convention celebrated with jubilee exercises. Dr. N. S. Davis of Chicago, founder of the Association, appeared on the stage escorted by the presidents of the state medical societies and the presidents of the state boards of medical examiners. Dr. John B. Roberts, chairman of the committee on anniversary exercises, presented Dr. Davis, calling attention to the fact that the fifty-two years that had passed since Dr. Davis's first step toward organization of the Association had been followed by the establishment of a higher standard of education and that there were now medical examining boards in nearly every state of the Union as well as state medical societies. President Senn greeted Dr. Davis on behalf of the Association; then Dr. Davis recited again a brief history of the organization, paying tribute to the many distinguished physicians who had participated in its work. Letters were presented from Drs. Atwater of Springfield, Mass., and John B. Johnson of St. Louis, who had been present at the first meeting.

At this session an action was taken offering a gold medal to members for meritorious work, establishing all addresses delivered before the entire Association as orations to distinguish them from the addresses of the chairmen of the sections and establishing an illustrated lecture to be read on the third evening devoted to some medical subject.

THE AUTHORITY OF THE BOARD

As the session ended, a few matters of great importance for the future of the Association were determined. One was a debate with final action on the decision that all actions of the Association requiring appropriation of funds must go to the Board of Trustees. This included even a motion to print 3,000 copies of the articles of incorporation, the Constitution and By-Laws and the Principles of Ethics.

DECISION BY A WITTICISM

Denver was chosen as the place of meeting. It is rather amusing that this decision was made as a result of a witticism. The competing communities were Columbus, Ohio; Tampa, Fla., and Birmingham, Ala. Those who had been urging Columbus prepared a map showing with what ease it could be reached from those centers. The delegate from Denver merely said "You will not need a map to find Denver."

ANIMAL EXPERIMENTATION

A significant address at this session was the statement by W. W. Keen beginning the campaign in which he was enlisted the rest of his life in behalf of experimentation on animals. The Association voted to send a reprint of that address to every Senator and Congressman. Dr. Keen reviewed the progress that had been made in medicine and surgery over fifty years. He credited this progress to the advance of medical teaching with the building of libraries and medical literature, the development of the allied medical sciences, the introduction of anesthesia, the development of antiseptic surgery, the rise of bacteriology and immunology, animal experimentation, and the use of instruments of precision. At one point in his address he said:

> Bacteriology would not now exist as a science, nor would accurate modern surgery and a large part of modern medicine be possible, had experiments upon animals been prohibited, as some zoophilous men and women who love dogs better than men and women, and even little children, desire.

He concluded his address with these paragraphs:

> We have discovered the actual cause of tetanus, tuberculosis, erysipelas, suppuration and a host of other diseases and conditions, of the cause of which we were wholly ignorant a few years ago. The causes of many other disorders, both medical and surgical, still remain hidden from our view. We know almost nothing of the origin of benign tumors and are groping to discover the origin of cancer, sarcoma and other malignant growths. When we have discovered the cause, we are nearly half way, or at least a long way, on the road to the discovery of the cure, and I think it not unlikely that in 1947 your then orator will be able to point to the time when a definite knowledge of the causes of these diseases was attained, and probably to a time when their cure was first instituted.
>
> That will be a surgical paradise when we can lay aside the knife and by means of suitable toxins or antitoxins, drugs or other methods of treatment control inflammation, arrest suppuration, stay the ravages of tuberculosis and syphilis, abort or disperse tumors, cure cancer and, it may be, so prolong human life that all of his then audience will die either of accident or old age. Would that you and I could be alive in 1947 to join in the glorious surgical Te Deum!

As the semicentennial passed, Leartus Connor wrote from Detroit congratulating the Association on a tremendous occasion and predicting that the sections and section work might one day be the chief function of the American Medical Association. He pointed out that the Association has one immense advantage over the special societies in the inexhaustible source of its membership.

Leartus Connor, particularly prominent in the affairs of the American Medical Association, was born in New York, Jan. 29, 1843. After graduation from Williams College in Massachusetts he taught for two years as an assistant principal in Mexico Academy of Mexico, N. Y. He studied under Dr. George L. Dayton and then during 1867-1868 in the medical department of the University of Michigan. From there he went to the College of Physicians and Surgeons in New York City and graduated in 1870. In 1871 he moved to Detroit to become teacher of chemistry in the Detroit Medical College, succeeding eventually to the positions of professor of physiology and clinical medicine and then professor of diseases of the eye and ear. At various times he edited a medical journal known as the *Detroit Review of Medicine and Pharmacy*, the *Detroit Medical Journal*, the *Detroit Lancet* and the *American Lancet*. For seven years he was secretary of the Association of American Medical Colleges. He had also been president of the American Academy of Medicine and of the American Medical Editors Association, chairman of the Section on Ophthalmology of the American Medical Association and vice president in 1882-1883 and a trustee from 1883 to 1889 and again from 1892 to 1894. He was president of the Michigan State Medical Society in 1902-1903 and chairman of its council from 1902 to 1905. He wrote widely in the field of medicine and contributed many biographies to the "Cyclopedia of American Medical Biography." Dr. Connor died on April 16, 1911.

MEDICAL PATENTS

An interesting item in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for Sept. 18, 1897 was an article entitled "Is It Ethical for Medical Men to Patent Medical Inventions?" It consisted largely of an attack on proprietary or "patent" medicines, and its tone in general was opposed to secrecy and patents in the field of medicine. When it was read many physicians arose to agree with the speaker. One of the most remarkable speeches was that of Dr. Squibb, founder of the house of E. R. Squibb & Sons. Dr. Squibb said:

> I do not myself think that anything should be patented by either physician or pharmacist. I am sure that the patient would not be benefited thereby. I may say in regard to "patent" medicines that the medical journals themselves are largely responsible for the existence of this class of remedies. If the journals would cease to distribute their advertisements, the sales would fall off 75 per cent. If editors of journals would use their influence to discourage the publication of such testimonials, it would be of great advantage.

1898

DENVER; THE SPANISH-AMERICAN WAR

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION began 1898 with an increased number of pages, a new press and some new type. The editor proposed particularly an increased amount of space for society proceedings. He called attention to the fact that some of the newest discoveries in medicine appeared in the proceedings of small societies and that it would be for the reader to differentiate between what was important and what was not.

The battle for animal experimentation had begun to enlist many of the great leaders of American medicine. Dr. William H. Welch of Johns Hopkins University contributed a notable essay citing his objections to the Gallinger bill. THE JOURNAL was urging doctors everywhere to reach their Congressmen and Senators with messages condemning this legislation.

Late in March THE JOURNAL appeared with an editorial on some medical questions of a possible war. It discussed the tremendous advances that had been made in military science and wondered whether or not human beings would be able to stand the high explosives and steel ships. "In case of hostilities, the sanitary problems on the island of Cuba will be many and full of interest," said the editor and, perhaps satirically, "The march through Spain from Cordova to Madrid will furnish much of interest to the medical profession." In April 1898 the coming of war in Cuba was the chief topic of interest. The editor of THE JOURNAL expressed little fear because Surgeon General Sternberg knew all about yellow fever and he gave good advice about boiling the water. "There is no question," he said, "but immunity from yellow fever can be secured by the rigid observation of sanitary regulations and prompt isolation of any infected case among the troops that may arise through carelessness or faulty hygiene." When the call for volunteers came, THE JOURNAL urged doctors to give their services. "As the number called out is small compared with the population of the country," said THE JOURNAL, "only well grown and perfectly sound men should be accepted."

RAILROAD RATES

There was great happiness in the profession because the railroads had finally given the doctors the same rates that they gave to members of the Christian

Again the question was raised as to the permanent secretary, and Dr. I. N. Love announced that he was not pushing the question. His announcement was greeted with applause. The Association had not yet developed a businesslike method for recording its membership or collecting its dues. There was a tremendous discussion over the fact that the railroad gave half rates to political bodies, synods and Christian Endeavor units but that the best the doctors could get was a fare and a third. In the midst of this discussion it was announced that President William McKinley was about to enter the hall. The proceedings state that:

> A moment or two later President McKinley came in arm in arm with Dr. Senn, who had returned to the rear of the stage to perform the office of escort, immediately after quieting down the Association. Dr. Hare preceded Dr. Senn and President McKinley; Mayor Warwick and Governor Hastings and Dr. Pepper and the others of the party attending President McKinley came after. The Association rose and cheered heartily for a minute or two. Quiet being restored, Dr. Senn presented President McKinley, who addressed the Association.

President McKinley merely conveyed greetings and stated that he had paused to pay respectful homage to the noble profession which those present so worthily represented.

Then a brilliant and witty address was made by Governor Hastings of Pennsylvania. A few quotations follow:

> We have all seen the ideal physician, whose presence in the sick room is as welcome as the morning sunshine; his voice is a benediction, his touch an inspiration and his presence an emblem of security To him children turn, and the marks of pain are changed into the expression of love and confidence. The aged reveal to him the secrets of their lives and their hopes of the life hereafter; mothers forget their vigils of the night in loving anticipation for the restoration of their revered or dear ones, or perhaps in the contemplation of the inevitable that the pathway to the tomb shall be strewn with roses in the confidence of a Redeemer's love.
>
> The development of medicine from a layman's point of view has been greater than that of any other science during the last hundred years. There was left a hiatus for a long period of time, when medicine appeared to be nothing but an empiric art. It is very, very different now. I was speaking to you a moment ago about the erection of statues or monuments to our great philanthropists, great soldiers, etc., and allow me to say that I think it is absolutely wrong and decidedly un-American that we do not erect monuments and statues to the great masters of medical science in this country. Then too I have been puzzled at the number of new diseases you have discovered. I read in a history of the fourteenth century by Horner something about diseases of the skin, in which he said there were three diseases of the skin. One was a disease which could be cured by the use of sulfur, a second disease of the skin could be cured by the use of mercury, and the other was a disease of the skin which the devil himself could not cure.

AGAIN CLEAN ADVERTISING

The Board of Trustees reported that some attempt to regulate the advertisements had resulted in a loss of nearly $4,000 because the advertisers felt that "the continued publication of a formula gives every druggist opportunity to enter into competition with the manufacturer of such specialties." The board put up to the Association its willingness to make some change in the manner and standard of advertising. There had been an increase in the membership of the Association. The board had invested $3,000 in a first mortgage on real estate in the city of Indianapolis. Because neither the Association nor the Board of Trustees was a chartered or legal corporation, the investment had to be made in the name of one of the board as trustee for the Association. Owing to a bank failure the funds of the Association had been placed in peril. This offered difficulties because the Board of Trustees did authorize that a charter should be secured. On motion the report was accepted and the action of the board in securing incorporation was concurred in.

The convention celebrated with jubilee exercises. Dr. N. S. Davis of Chicago, founder of the Association, appeared on the stage escorted by the presidents of the state medical societies and the presidents of the state boards of medical examiners. Dr. John B. Roberts, chairman of the committee on anniversary exercises, presented Dr. Davis, calling attention to the fact that the fifty-two years that had passed since Dr. Davis's first step toward organization of the Association had been followed by the establishment of a higher standard of education and that there were now medical examining boards in nearly every state of the Union as well as state medical societies. President Senn greeted Dr. Davis on behalf of the Association; then Dr. Davis recited again a brief history of the organization, paying tribute to the many distinguished physicians who had participated in its work. Letters were presented from Drs. Atwater of Springfield, Mass., and John B. Johnson of St. Louis, who had been present at the first meeting.

At this session an action was taken offering a gold medal to members for meritorious work, establishing all addresses delivered before the entire Association as orations to distinguish them from the addresses of the chairmen of the sections and establishing an illustrated lecture to be read on the third evening devoted to some medical subject.

THE AUTHORITY OF THE BOARD

As the session ended, a few matters of great importance for the future of the Association were determined. One was a debate with final action on the decision that all actions of the Association requiring appropriation of funds must go to the Board of Trustees. This included even a motion to print 3,000 copies of the articles of incorporation, the Constitution and By-Laws and the Principles of Ethics.

DECISION BY A WITTICISM

Denver was chosen as the place of meeting. It is rather amusing that this decision was made as a result of a witticism. The competing communities were Columbus, Ohio; Tampa, Fla., and Birmingham, Ala. Those who had been urging Columbus prepared a map showing with what ease it could be reached from those centers. If editors of journals would use their influence to discourage the publication of such testimonials, it would be of great advantage.

1898

DENVER; THE SPANISH-AMERICAN WAR

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION began 1898 with an increased number of pages, a new press and some new type. The editor proposed particularly an increased amount of space for society proceedings. He called attention to the fact that some of the newest discoveries in medicine appeared in the proceedings of small societies and that it would be for the reader to differentiate between what was important and what was not.

The battle for animal experimentation had begun to enlist many of the great leaders of American medicine. Dr. William H. Welch of Johns Hopkins University contributed a notable essay citing his objections to the Gallinger bill. THE JOURNAL was urging doctors everywhere to reach their Congressmen and Senators with messages condemning this legislation.

Late in March THE JOURNAL appeared with an editorial on some medical questions of a possible war. It discussed the tremendous advances that had been made in military science and wondered whether or not human beings would be able to stand the high explosives and steel chips. "In case of hostilities, the sanitary problems on the island of Cuba will be many and full of interest," said the editor and, perhaps satirically, "The march through Spain from Cordova to Madrid will furnish much of interest to the medical profession." In April 1898 the coming of war in Cuba was the chief topic of interest. The editor of THE JOURNAL expressed little fear because Surgeon General Sternberg knew all about yellow fever and he gave good advice about boiling the water. "There is no question," he said, "but immunity from yellow fever can be secured by the rigid observation of sanitary regulations and prompt isolation of any infected case among the troops that may arise through carelessness or faulty hygiene." When the call for volunteers came, THE JOURNAL urged doctors to give their services. "As the number called out is small compared with the population of the country," said THE JOURNAL, "only well grown and perfectly sound men should be accepted."

RAILROAD RATES

There was great happiness in the profession because the railroads had finally given the doctors the same rates that they gave to members of the Christian

Endeavor for their conventions. The trip to Denver would cost only one way fare plus $2.

When the Association met in Denver, President Sternberg was unable to be present because his official duties kept him in Washington. His address was read for him by Colonel Woodhull of the U. S. Army. In the address George M. Sternberg discussed the progress of medical science. He encouraged the proposal for the establishment of an organization of defense of medical research. He spoke learnedly about the importance of evaluating negative evidence as well as that favorable to new discoveries. He urged greater attention to the use of the laboratory and greater study of the basic sciences. And he concluded that what had been said "would show that there is no room for creeds and pathies in medicine, any more than in astronomy, geology or botany."

In the June issues of The Journal, Lieut. Col. Nicholas Senn of the National Guard and Illinois Volunteers began his War Correspondence, which was to be a significant feature of The Journal during the Spanish-American War.

Now The Journal began printing weekly comments to the effect that the secretary of the business committee, Dr. Bulkley, had failed to turn in the minutes. The permanent secretary had to share the responsibility. In fact, the editor of The Journal said that it was up to the permanent secretary to see to it that the intense desire of the business committee to conduct the affairs of the Association did not lead its manager to suppress the minutes altogether. Probably the minutes arrived late, because a goodly share of them appeared in the same number in which the editorial complaint is printed.

By this time the technical business of the Association had become so complicated that there began to be complaints that the delegates had no opportunity to attend the scientific meetings. An attempt was made to work out an hourly schedule that would satisfy every one.

Some letters were sent to the editor explaining what had happened to the minutes, and the editor reproved Dr. L. D. Bulkley, telling him that the minutes were the property of the Association and that he had no right to carry them away.

Dr. Richard French Stone of Indianapolis reported that he had worked out a badge for the Association and had it patented so that it would be under the control of the Association. It was an interesting design including a circular spear with a pointed cross. Eventually this design was not adopted.

Dr. William Bailey of Louisville, Ky., offered a resolution to the effect that an active secretary, who could devote his whole time to the work, should be appointed at a salary not exceeding $3,000 a year to work under the present business committee and that the present permanent secretary be retained with the title "honorary secretary." The business committee recommended that his resolution lie over for one year and stated that it would propose changes in the Constitution and By-Laws for the next session. The matter was referred to the Board of Trustees. Out of this came the employment of Dr. George H. Simmons, who was to be the most important force for the next two decades in placing the American Medical Association on the road to financial success and leadership of American medicine.

A motion was passed for the preparation of a membership button.

At the fourth general session there was still more debate over the minutes, which Dr. I. N. Love insisted were not correctly presented. Members insisted that the reporter was incompetent. Dr. Atkinson was bitterly criticized for leaving out portions of the minutes in his reading. Dr. Atkinson became annoyed and said there would be no trouble in keeping the minutes if the doctors would write out their resolutions and turn them in. The end result was an affirmation of the desirability for having a secretary elected annually and for having an accurate report on the minutes day by day.

Another resolution tried to bring about peace with the disaffected medical societies of New York by rescinding all previous actions in relationship to them. Still another resolution proposed to appoint a committee to go over all textbooks in the field of physiology and hygiene in order to make sure of correctness in their statements. Again came the resolution that all officers of the Association be elected for one year. This was laid on the table.

THE BOARD OF TRUSTEES

The report of the Board of Trustees was exceptional in that it was for the first time a complete statement of comparison of the accomplishments of The Journal with other publications. It was now clear that The Journal of the American Medical Association was publishing more material than other medical periodicals in the United States but was not carrying nearly as much advertising as the *Boston Medical and Surgical Journal* or the *New York Medical Journal* and the *New York Medical Record.* It was estimated that the ruling on proprietary medicines was causing The Journal a loss of from $8,000 to $10,000 annually, but was nevertheless successful. The Association had accumulated a great deal of property in the way of machinery and office furniture and it put another $10,000 in the investment fund.

Now Dr. Gihon was able to report that the Rush monument fund had tripled and he now had nearly $12,000.

At this time the Board of Trustees had recommended to the Association that any place that wanted to hold the meeting would have to supply the necessary halls free of expense to the Association.

Practically all resolutions had been referred to the business committee, which rejected the proposal to include anything about the textbooks. The committee put back to the Association as a whole the question of bringing back the New York physicians. Dr. Hobart E. Hare, in an important address, explained the difficulties that prevailed. Dr. X. C. Scott of Cleveland in a reply called attention to the effect that the difficulties with New York involved the Code of Ethics. He was supported by Dr. E. D. Ferguson. There was great heat engendered over this debate with shouts of "No! No!" and "Yes! Yes!" and with cries of "Good! Good!" Dr. W. P. Munn of Denver spoke passionately and concluded "We have all we can do to keep out the dead rot of commercialism and are we going to be trodden down by this derelict, dead, rotten society of New York, which is continually sending" [cries of "No!" mingled with hisses, the final words of the sentence being inaudible]. Dr. Edward Jackson of Philadelphia hoped that the question would be settled once and for all. Then the question was settled by Dr. W. T. Bishop of Harrisburg, Pa., who pointed out that there could be only one state society in any state and there were two in New York and until New York got together there was no chance to settle the question.

DEATH OF DR. JOHN B. HAMILTON

The issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION dated Dec. 31, 1898 opened its editorial column with a black border and the words:

> It is our painful duty to record the death of the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION on the evening of Dec. 24, 1898 at his residence at Elgin, Ill. The immediate cause of his decease was hemorrhage from a perforation of the intestine, communicating with a large abscess outside the bowel, which terminated life after an illness of less than one month.

The concluding paragraphs tell the story of the terrific work in which he engaged during his later years:

> The leading sanitarian of the country, in all matters of national interest, his advice was sought in every quarter. No medical gathering of national or international importance was complete without his presence. His vigorous form, his genial countenance, radiant with energy and good will, his persuasive voice, were never to be forgotten features in every such assembly. At home his professional duties, his hospital work, his extensive private practice were enough to wear out any ordinary man; but he was ever ready to expend his energies in behalf of any worthy cause that appealed to him for aid. In this way he gave much time and thought to the organization of the new Public Library in Chicago and was most efficient as President of its Board of Trustees. To the surprise of his friends, despite this accumulation of cares, he accepted, in 1896-1897, the position of superintendent of the Northern Illinois Hospital for the Insane, at Elgin, Ill.—an office that heretofore was always considered sufficient to occupy the whole time of an ordinary official incumbent. But the Doctor speedily showed his mettle by a reorganization of the administration that secured improvement in the care of patients, while leaving time for all his other labors—thus illustrating the old observation that among first class administrators the busiest men still have the most leisure.
>
> Now, alas, this career of action has reached its limit. As we look back upon its years we can more fully than ever appreciate its magnitude and its beneficent efficiency. Dr. Hamilton was fortunate in finding full scope for his remarkable power as a founder and organizer of incipient enterprises. He was fortunate also in being permitted to witness the success of his efforts, and he was doubly fortunate in being called to his reward before age or misfortune or any of the ills of life could dim the splendor of his reputation. He has gone, but his works live and will forever exhibit the impress of his constructive power.

1899

COLUMBUS, OHIO

The first volume for the year 1899 contains a title page which indicates that it was edited for the Association under the direction of the Board of Trustees by George H. Simmons, A.M., M.D. This notice was to continue for the next twenty-five years. There are many stories relative to the selection of Dr. George H. Simmons as editor of THE JOURNAL. The report of the Board of Trustees simply says:

> For the last three months of the year the management was greatly embarrassed by the sickness and death of the late editor, Dr. John B. Hamilton. Under his personal supervision THE JOURNAL had increased to nearly three times its original subscription and had gradually obtained a well equipped plant and a large reserve fund but, more than all, a recognized position among tthe reputable journals of the country.
>
> On Jan. 1, 1899, shortly after the announcement of the death of Dr. Hamilton, a called meeting of the Board of Trustees was held, at which it was resolved to continue the conduct of THE JOURNAL business under the direction of the resident trustee, Dr. Truman W. Miller, who had very generously, at the sacrifice of his own interests, assumed the management, on the demise of the editor. At the direction of the Board he had the accounts of THE JOURNAL office and the treasurer examined by an expert accountant, who pronounced them correct. At the annual meeting of the Board, February 17 last, after a careful canvass of the available editorial material, Dr. George H. Simmons of Lincoln, Neb., was chosen editor for one year, at a salary of $5,000, with the stipulation that he should move to Chicago and devote his whole time to the work of THE JOURNAL. Your Board congratulates itself that the wisdom of its selection as editor has been efficiently demonstrated by the subsequent progress of THE JOURNAL. The changes that have been made render it more valuable to its patrons and justify the hope of the Board that it shall become the representative medical journal of the world. Other progressive features are under contemplation. A better grade of white paper will be used in the next volume, and the Board has authorized the purchase of two Mergenthaler linotype machines, at an expense of $6,700, which will insure the use of new type for every issue.

Later in this history a chapter will deal with the details of the life and of the work of Dr. George H. Simmons. According to the best available evidence he was chosen from a considerable group of candidates whose names had been suggested from time to time for the position, including such men as Drs. Bayard Holmes, Harold N. Moyer, Ludvig Hektoen, George M. Gould, G. Frank Lydston and P. Maxwell Foshay. Many of them were interviewed personally by the Board of Trustees. It is understood that Dr. Simmons had the special support of Dr. J. T. Priestly of Iowa and Dr. Joseph Eastman of Indianapolis, who had recognized the merit of his work in the Western Surgical Association.

In 1898 a new weekly Philadelphia medical journal was launched with the financial backing of Musser, Keen, Osler and many others, with George M. Gould as editor. In writing to Musser about that time William Osler said "The J. A. M. A. needs him now more than we do and he could put THE JOURNAL on a first class basis which would be a good thing for the rank and file."

The Board of Trustees discussed the action that had been taken relative to the choice of a full time secretary. It appeared that the minutes of previous action were in such confusion that it was impossible for the Board of Trustees to find their way to a definite conclusion. The Board of Trustees recommended, therefore, an amendment to the Constitution to the effect that the editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION should be the secretary of the Association and should serve as such without additional compensation. It was felt that this would be an economical and efficient procedure, since the secretary would have charge of the manuscripts, which he could then turn over to himself in the position of editor. When the Board of Trustees presented this report, Dr. W. B. Atkinson took exception to the statement concerning the confusion in the minutes. He was answered by Dr. T. J. Happel of Tennessee, member of the Board of Trustees, who stated that the trustees had made careful study but had been unable to find minutes sufficient to indicate exactly what the Association had done in the matter in question. The motion was put and carried. Thus Dr. Simmons on June 7, 1899 was confirmed by the Association as editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and as its secretary.

In the period between the death of Dr. Hamilton in December and the time of the meeting of the Board of Trustees in February 1899 THE JOURNAL was conducted under the direction of the resident secretary of the Board of Trustees, Dr. Truman W. Miller, Chicago.

Dr. Truman W. Miller died in 1900 at the age of 60. He had received his medical education at the College of Physicians and Surgeons of New York and his degree of M.D. from the Geneva Medical College. He served in the Civil War and in 1873 was appointed Assistant Surgeon in the U. S. Marine-Hospital Service. In 1877 he was promoted to Surgeon and resigned in 1886. He had served on the staffs of many of Chicago's prominent hospitals. Known as a man of action not much given to writing or speaking but known for a pertinacity of purpose and executive ability, he originated the Chicago Polyclinic.

Significantly, with the assumption by Dr. Simmons of the position of secretary-editor the list of editorial contributors, assistants and other members of the staff of the headquarters office of the American Medical Association disappeared from the pages of THE JOURNAL. Dr. Simmons assumed management of the headquarters office on March 1. THE JOURNAL proceeded without missing a page or an issue. It is not possible to observe any significant changes in the publication from the period of Hamilton until the issue of March 18, when the editorial columns began to contain a number of small notations on medical affairs, now published under the title of "Current Comment." The popularity of these minor comments is indicated by their continuance since that date. In March a department of medical news was introduced into THE JOURNAL and also a section of questions and answers. In April the department of current medical literature was established, with a listing of the contents of other medical publications and abstracts of significant articles. These features have been continuously in THE JOURNAL since that time.

Two interesting articles appeared in THE JOURNAL in April 1899 and are an indication of the trend of thought of the period. The leading article for April 1 was entitled "Some of the Minor Immoralities of the Tobacco Habit." The hygiene of the period was becoming even more teetotalitarian. Here is a paragraph from this extraordinary scientific contribution:

> The vulgarity and licentiousness of the press, with its mercenary pandering to vice, corrupting as it does that very fountain of national strength, the home; the lubricity, the demoralizing baseness of the degraded drama, disfigurement of hoardings by the cigaret-soaked indecencies of the variety stage, making it difficult for our children to walk the streets without contamination, the growing fondness for certain social functions with their flimsy vaudeville adornments, the mockery of and attempted obliteration of personal puritanism, the crass things done by tobacco-biased young people, degradation of seats of learning by the introduction of smoking-rooms, those hotbeds of vice and agnosticism, of ballet dancing and brainless burlesque —imbecility and irreverence under the auspices of fashion— defilement of public buildings by foul receptacles provided for a people so base that it is necessary to ask them to please not spit on the floor, the Negro minstrel methods of some of our churches, the effeminacy of religious periodicals with their venal advocacy of successful quackery and fraud, the prevalence of the gambling mania among women, leveling all ranks, wasting energy, dissipating time so much needed in more ennobling ways, medieval grotesqueries, euchre and wine parties for the spiritual and physical benefit of the outcast and sick, made so by gambling and drink! what, unless completely engrossed in other things, could induce thoughtful men to silently submit to these, but that undiscriminating drowsiness of conscience—"denying nothing, doubting everything," so frequently induced by tobacco?

Another article in an April issue was by Charles J. Whalen of Illinois and dealt with the doctor as a politician. It was a plea that physicians enter politics in order to secure needed medical reforms and politics was an avocation for Dr. Whalen until the end of his interesting career in medical affairs.

Under Dr. Simmons' editorship THE JOURNAL began to assume more definite form and departmentalization. The interest of the members is shown in many letters published as correspondence to the editor. The space devoted to society proceedings was greatly elaborated, as was also the space devoted to editorials and comments.

In 1899 the publication of the *Index Medicus* was discontinued because of lack of funds. THE JOURNAL, as well as other publications elsewhere in the world, expressed sorrow but it was not for many years that restoration of this publication to its present high estate was attempted.

In the May 27, 1899 issue, for the first time, appeared a well ordered announcement of the next annual session of the American Medical Association in Columbus, Ohio, with a map of the center of Columbus, full information regarding transportation, hotels and other data necessary to those who would attend the meeting. A feature of the issue of June 3, 1899 was a review of the previous presidents of the American Medical Association with photographs of many of them and a list of the meetings and those who presided. This interesting feature was contributed by Nathan Smith Davis.

A supplement to THE JOURNAL recorded progress in surgery for fifty years by Rudolph W. Matas and progress in medicine by John H. Musser, in gynecology by Charles A. L. Reed, in obstetrics by Frank Stahl, in therapeutics by Hobart A. Hare, in physiology by G. N. Stewart, in anatomy by Frank Baker, in pathology by J. Rilus Eastman, in ophthalmology by Casey A. Wood, in otology by T. Melville Hardie, in laryngology by E. Fletcher Ingals and in neurology and psychiatry by a writer whose name for some reason was not given.

There were biographies of the officers of the Association, including the chairman of the Board of Trustees, Dr. Alonzo Garcelon, a complete list of previous members of the Board of Trustees with a group photograph, a brief history of THE JOURNAL and a review of the existing medical periodicals and medical colleges of the country. All this material was included in a special supplement to THE JOURNAL which made it a souvenir number. An editorial reviewed the great progress that had been made in American medicine.

In his president's address Dr. Joseph M. Mathews of Louisville, Ky., made a plea for the removal of the headquarters of the Association to Washington. He thought that it was a mistake to refuse to publish in THE JOURNAL any article read in the Association and that it was up to the readers to select the good from the bad. Dr. Mathews made the suggestion that there be a field secretary to travel about the country and to increase its membership, at the same time soliciting subscriptions to THE JOURNAL. This was to be the most significant of his recommendations. The action favorably taken ultimately on this recommendation led to the most significant steps in reorganization and improvement of membership.

Notwithstanding the tremendous enthusiasm and the numerous contributions that had been made at the 1897 meeting held in Philadelphia, the Rush monument fund had reached only $10,082.52. Dr. Albert L. Gihon announced that he was leaving for an indefinite residency abroad and resigned as leader for this fund.

The Association had up to this time reached an annual budget of a little over $83,000, and it had more than $18,000 in the treasury.

The Association was urging the employment of women nurses in military hospitals. It urged increased rank for the Surgeon General of the Army, support for the *Index Medicus*, and the creation of a national department of public health with a cabinet minister.

A committee was appointed to revise the Constitution and By-Laws. On recommendation of the executive committee the Association voted not to hold its meetings permanently in Washington and that it avoid too many entertainments. The recommendation for a traveling assistant secretary was referred to the Board of Trustees. Actions were taken to make a special review of tuberculosis and urged the development of sanatoriums and to urge compulsory vaccination against smallpox. A motion had been introduced that there be published a list of members of the Association. This was opposed on the ground that this list would be used by the proprietary drug houses for commercial purposes. Dr. Simmons rose for the first time in the House of Delegates and defended the publication of the list on the grounds that he could sell it for $25 a copy. However, the entire consideration was finally laid on the table.

THE SCIENTIFIC EXHIBIT

Among the most significant and important developments for the advancement of medical science has been the Scientific Exhibit. Today it occupies many thousands of square feet of space and has been characterized as the most valuable effort in behalf of graduate medical education attempted by any organization anywhere in the world. It started with small and simple beginnings. At the meeting of the American Medical Association in 1899 a resolution was introduced by Dr. Charles E. Slocum of Defiance, Ohio, in which he said "that this Association hereby commends the efforts of the Indiana State Medical Society in preserving pathologic specimens and exhibiting the same at this meeting. This exhibit is worthy the attention of every member, being a good example of what careful and persistent attention to pathology may accomplish in a short time when well directed. Such efforts are recommended to all societies as conducive to more careful and methodic diagnosis of treatment." On motion this resolution was adopted.

THE JOURNAL INDEX

The quality of the index to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION notably improved with the second half of 1899 and has come to be recognized as one of the most important general indexes in the field of medicine. With the complete coverage of medical science represented by THE JOURNAL, this index is for most workers in the field of medical biography the first line of attack.

DR. BILLINGS BECOMES ACTIVE

Dr. Frank Billings was chairman of the Section on Medicine in 1899. There were eighty-three papers, and he had succeeded in securing fifty-four abstracts. He made the suggestion that a rule be adopted requiring every member who desires to prepare and present a paper at any future meeting to prepare and send to the officer of the section a short synopsis of the paper to be printed in advance of the meeting. He urged that, if possible, the papers should concern original research, but he recognized the value of full reports of cases when possible supported by thorough postmortem examinations.

NEW PROGRESS THROUGH THE JOURNAL

The differences and disagreements in American medicine were being harmoniously resolved. The quality of THE JOURNAL began to improve. Membership was increasing, as were subscriptions to THE JOURNAL. Dr. Hamilton had been a competent editor, but the quality of the new leadership was clearly apparent. Following leadership by the Chicago *Tribune*, THE JOURNAL began a campaign against Fourth of July accidents, initiating its campaign with an editorial which was to be followed some years later by a careful survey of deaths and accidents as seen by physicians and hospitals throughout the nation.

The enterprise of THE JOURNAL was indicated by publication of the proceedings of the Canadian Medical Association on the same day on which the meeting occurred and distributing it among the Canadian members. The button for the Association was developed following the design originally worked out by Dr. Richard French Stone. This design was later to be discarded for the one now followed.

During the year an attempt was made in Germany to produce an Index Medicus under the name of "Index Medicus Novus." It proved to be a weak effort and quite incapable of replacing the *Index Medicus* that had been developed by John Shaw Billings and Robert Fletcher.

THE SCIENTIFIC EXHIBIT

Gradually new departments such as clinical reports and therapeutic notes were added to THE JOURNAL. In THE JOURNAL for Dec. 2, 1899, Dr. Frank B. Wynn of Indianapolis wrote to the editor about the Scientific Exhibit. In 1897 an appeal had been made to members of the Indiana State Medical Society for pathologic specimens, and at each annual meeting since that date such specimens have been exhibited, reaching 800 in 1899. The exhibit had attracted so much attention in Indiana that the state society appropriated $300 to take the exhibit to the Columbus meeting of the American Medical Association. Dr. Wynn urged a similar exhibit for each meeting of the American Medical Association and together with such an exhibit the establishment of a section on pathology. He felt that there should be a similar exhibit every year and, he concluded, "in seeking to inaugurate a pathologic museum, the executive officers of the American Medical Association should receive the enthusiastic support of every member of the organization. Start the movement at once! Have an exhibit at Atlantic City next year, even if it is a small one! Let us have a wholesome direction from the selfish commercial exhibits! In conclusion, let me say that Indiana, as the pioneer in this field, stands ready to meet the requirement put on her by the national body."

And still THE JOURNAL improved, with special headings of news and center headings of London, Philadelphia and New York, with improved pictures sometimes occupying full pages. A department of New Instruments was added. The prominence of the consideration given to new discoveries and new activities indicated a journalistic quality in the editor that was in advance of his time.

Clinical Notes, Suggestions and New Instruments

UNILATERAL FRONTAL HYPERHIDROSIS RELIEVED BY SUPRAORBITAL NERVE SECTION

J. M. TAYLOR, M.D.
and
ERNST HERZ, M.D.
New York

Disturbances of sweating in areas supplied by peripheral nerves have been described in association with lesions of these nerves and always in the presence of abnormalities of sensory or motor functions. There have been numerous observations[1] *of either hyperhidrosis or anhidrosis in cases of traumatic lesions of peripheral nerves. However, the occurrence of hyperhidrosis in the zone of supply of a peripheral nerve in the absence of any accompanying abnormality of function has not hitherto been recorded, to our knowledge. Further justification for this report is the fact that the patient was relieved of her complaint by division of the nerve supplying the affected area.*

The patient was a rather tense woman, 30 years of age, the mother of three children, aged 8, 4 and 1½ years. General physical as well as neurologic examinations did not reveal any abnormality except for a disturbance of sweating over the left side of the forehead. The exact outline of this area was determined by measuring the electrical skin resistance with a Dermohmeter on the day of the operation, when droplets of sweat covered the left side of the forehead. The area of decreased electrical skin resistance (fig. 1) corresponded closely with the zone of increased sweating (fig. 2). This zone represents the cutaneous area supplied by the supraorbital nerve with respect to both its sensory and also its sudomotor innervation as determined by the Minor starch method (fig. 3).

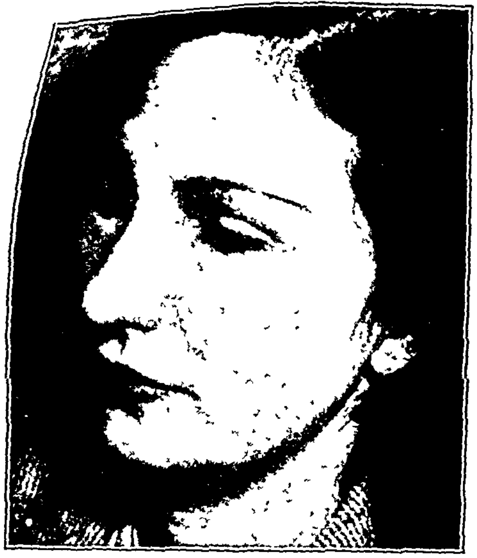

Fig. 2.—Increased sweating on left side of the forehead.

Section of the supraorbital nerve was therefore recommended and readily accepted by the patient, who was severely embarrassed by her complaint. On March 14, 1946 under local procaine hydrochloride anesthesia the left supraorbital nerve persistent sweating which occurs over a small zone covering the area of a five cent piece just above and medial to the inner border of the eyebrow. This hyperhidrosis occurs under the same circumstances now as before the operation, but it is slight and does not cause the patient embarrassment.

Examination of the electrical skin resistance on June 11, 1946 revealed an area of increased resistance with complete loss of sensation and a remaining small zone of decreased resistance without sensory disturbance (fig. 3). At the time of the last examination (July 17, 1946) the area of decreased resistance had vanished, and there was only hypesthesia in the former area.

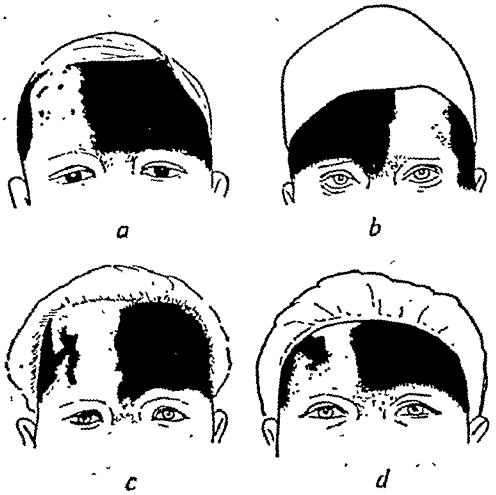

Fig. 4.—Disturbance of sweat secretion in lesions of the supraorbital nerve (after L. Guttman); investigated by Minor's iodine starch method.

COMMENT

The result of the operation, which consisted solely of resection of the supraorbital nerve with preservation of the adjacent artery, confirms the conclusions of List and Peet[2] with reference to the course of the sweat fibers to the forehead (fig. 5).

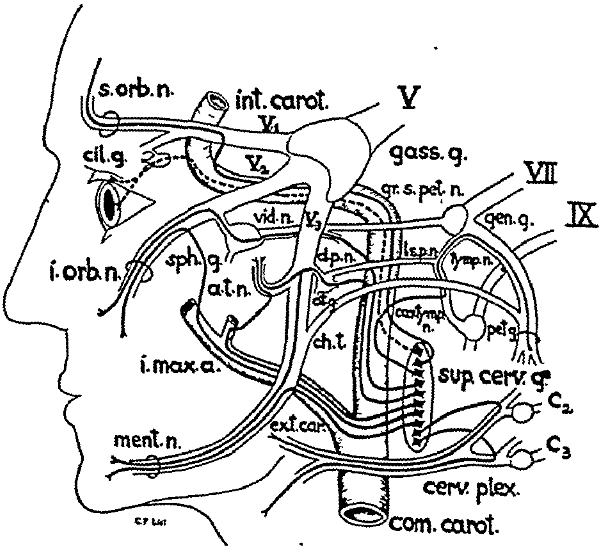

Fig. 5.—Schematic drawing illustrating the probable course of the sympathetic sweat fibers for the face (after List and Peet).

The autonomic fibers from the superior cervical ganglion finally join the branches of the trigeminal nerve shortly before their points of exit through the skull. After section of the supraorbital nerve the interruption of sweating and sensory function in the corresponding area was complete. Sensation was partly restored four months after the operation. With regard to the persistence of sweating and the associated decrease in the electrical skin resistance in the small area shown in figure 3, it is possible that a small branch of the supraorbital nerve supplying this region was not severed at operation.

An apparent reason for the spontaneous occurrence of hyperhidrosis in the area of the supraorbital nerve could not be found. The patient never experienced pain, and a history of trauma to the nerve or of any infectious process in the region of it was lacking. The etiology and pathogenesis of the condition remain unknown. However, one might assume the presence of an irritative process affecting solely the autonomic fibers of a sensory nerve. Further investigation of electrical skin resistance in cases of neuralgia and circumscribed cutaneous conditions may reveal comparable abnormalities of autonomic innervation.

SUMMARY

A case of circumscribed hyperhidrosis over the left side of the forehead is described. After section of the supraorbital nerve the hyperhidrosis was abolished almost completely. The area of disturbed sweating was clearly outlined by measurement of the electrical skin resistance. The result of the operation confirms the conclusion of List and Peet on the course of sweat fibers to the forehead.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1946, p. 436).

The following dosage forms have been accepted:

THE HARROWER LABORATORY, INC., GLENDALE, CALIF.

Diethylstilbestrol (in Peanut oil): 1.0 mg. per cc.: 1 cc. ampuls, and 5.0 mg. per cc.: 10 cc. vials, preserved with 0.5 per cent chlorobutanol.

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Tablets Diethylstilbestrol: 0.1 mg., 0.5 mg. and 1.0 mg.

PREMO PHARMACEUTICAL LABORATORIES, INC., NEW YORK

Diethylstilbestrol (in Peanut oil): 0.5 mg. per cc., 1.0 mg. per cc. and 5.0 mg. per cc.: 1 cc. ampuls.

Vaginal Suppositories Diethylstilbestrol: 0.1 mg. and 0.5 mg. Tablets Diethylstilbestrol: 0.1 mg., 0.5 mg., 1.0 mg. and 5.0 mg.

THE VALE CHEMICAL CO., INC., ALLENTOWN, PA.

Tablets Diethylstilbestrol: 0.1 mg., 0.5 mg. and 1.0 mg.

PENICILLIN IN OIL AND WAX (See THE JOURNAL, Sept. 7, 1946, p. 23).

The following dosage forms have been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Penicillin (Calcium) in Oil and Wax: 300,000 units per cubic centimeter in B-D[1] 1 cc. glass cartridge with B-D Disposable Cartridge Syringe; and in B-D 1 cc. cartridge, with flushing fluid (benzyl alcohol 1.5 per cent in isotonic solution of sodium chloride), for use in B-D Cartridge Syringe. Calcium penicillin suspended in peanut oil containing 4.8 per cent (W/V) white wax, U. S. P.

THE WM. S. MERRELL CO., CINCINNATI

Penicillin (Calcium) in Oil and Wax: 300,000 units per cubic centimeter, 10 cc. vials. Calcium penicillin suspended in peanut oil containing 4.8 per cent white wax, U. S. P.

WYETH INCORPORATED, PHILADELPHIA

Tubex Penicillin (Calcium) in Oil and Wax: 300,000 units per cubic centimeter. Penicillin calcium suspended in peanut oil containing 4.8 per cent yellow wax, U. S. P.

UNILATERAL FRONTAL HYPERHIDROSIS RELIEVED BY SUPRAORBITAL NERVE SECTION

I. M TARLOV, M D
and
ERNST HERZ, M D.
New York

Disturbances of sweating in areas supplied by peripheral nerves have been described in association with lesions of these nerves but always in the presence of abnormalities of sensory or motor functions There have been numerous observations[1] of either hyperhidrosis or anhidrosis in cases of traumatic lesions of peripheral nerves. However, the occurrence of hyperhidrosis in the zone of supply of a peripheral nerve in the absence of any accompanying abnormality of function has not hitherto been recorded, to our knowledge. Further justification for this report is the fact that the patient was relieved *of her complaint by division of the nerve supplying the affected* area.

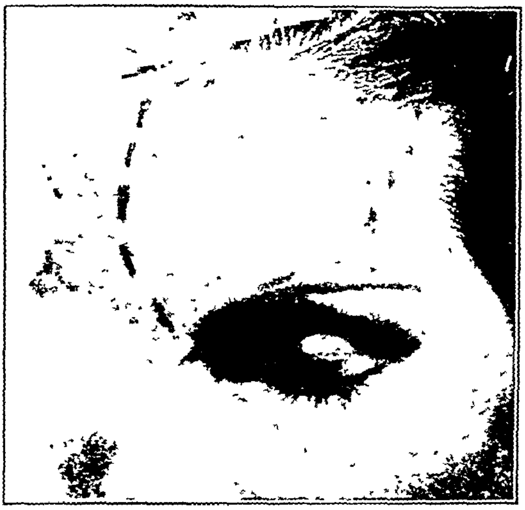

Fig 1 —Area of decreased electrical skin resistance before operation.

REPORT OF CASE

Mrs E M, aged 30, referred by Dr Grace Gorham of Norwalk, Conn, suffered from paroxysms of sweating over the left side of the forehead Her family and past histories were noncontributory except that she and three other members of her family have always been "rather nervous" At the age of 16 years she noticed attacks of sweating "along the inner side of my left eyebrow" Gradually in the course of the next few years the area of perspiration spread to involve the entire left side of her forehead. The disturbance was precipitated by unpleasant thoughts or excitement. "Just reading a murder mystery would bring it on; any sort of emotion, even joy, would cause it. Visiting friends or going out to dinner or playing bridge was most embarrassing to me, because I would have to hold a handkerchief in my hand and keep constantly mopping my brow. It got so bad that I dreaded going out socially. On damp days I noticed that the perspiration might keep coming all day long. It was always on the left side of my forehead Sometimes being in a draft would start the sweating."

The patient was a rather tense woman, 30 years of age, the mother of three children, aged 8, 4 and 1½ years. General physical as well as neurologic examinations did not reveal any abnormality except for a disturbance of sweating over the *left side of the forehead* The exact outline of this area was determined by measuring the electrical skin resistance with a Dermohmeter on the day of the operation, when droplets of sweat covered the left side of the forehead. The area of decreased electrical skin resistance (fig. 1) corresponded closely with the zone of increased sweating (fig. 2). This zone represents the cutaneous area supplied by the supraorbital nerve *with* respect to both its sensory and also its sudomotor innervation as determined by the Minor starch method (fig. 3).

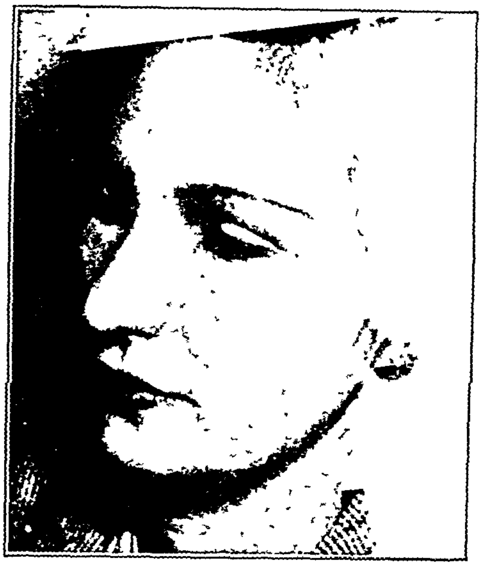

Fig 2 —Increased sweating on left side of the forehead

Section of the supraorbital nerve was therefore recommended and readily accepted by the patient, who was severely embarrassed by her complaint On March 14, 1946 under local procaine hydrochloride anesthesia the left supraorbital nerve was exposed and separated from the artery, and a section of the nerve about 1 cm long was excised The artery remained undamaged. The wound was closed with silk sutures, which were removed on the fourth postoperative day. Healing of the wound was prompt. Since the operation the patient has been relieved of her paroxysms of perspiration, except for slight

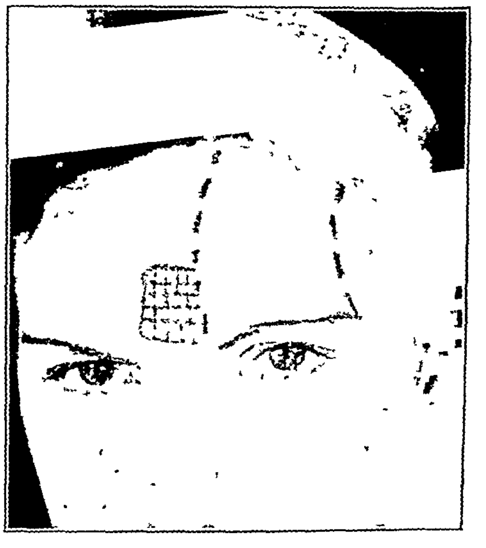

Fig 3 —Area of anesthesia and increased electrical skin resistance and small (cross hatched) area of remaining increased skin resistance after operation

---

From the Department of Neurosurgery, New York Medical College, and the Department of Neurology, Columbia University College of Physicians and Surgeons and the Neurological Institute of New York.

Jasper, H., and Robb, P.: Studies of Electrical Skin Resistance in Peripheral Nerve Lesions, J. Neurosurg 2:261 (July) 1945. Herz, E; Glaser, G H; Moldaver, J, and Hoen, T. I.: The Electrical Skin Resistance Test in the Evaluation of Peripheral Nerve Injuries, *Arch. Neurol & Psychiat.* 56:365 (Oct) 1946

persistent sweating which occurs over a small zone covering the area of a five cent piece just above and medial to the inner border of the eyebrow. This hyperhidrosis occurs under the same circumstances now as before the operation, but it is slight and does not cause the patient embarrassment.

Examination of the electrical skin resistance on June 11, 1946 revealed an area of increased resistance with complete loss of sensation and a remaining small zone of decreased resistance without sensory disturbance (fig. 3). At the time of the last examination (July 17, 1946) the area of decreased resistance had vanished, and there was only hypesthesia in the former area.

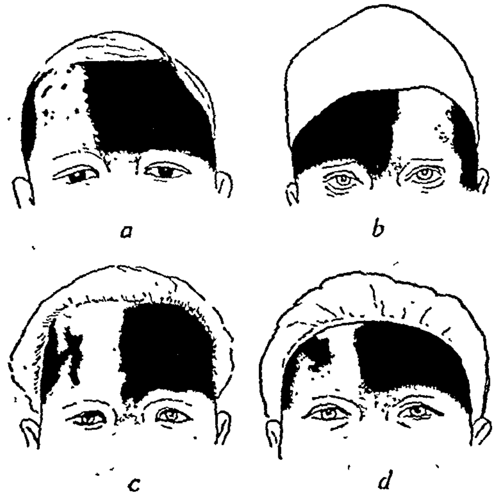

Fig. 4.—Disturbance of sweat secretion in lesions of the supraorbital nerve (after L. Guttman); investigated by Minor's iodine starch method.

COMMENT

The result of the operation, which consisted solely of resection of the supraorbital nerve with preservation of the adjacent artery, confirms the conclusions of List and Peet[2] with reference to the course of the sweat fibers to the forehead (fig. 5). The autonomic fibers from the superior cervical ganglion finally join the branches of the trigeminal nerve shortly before their points of exit through the skull. After section of the supraorbital nerve the interruption of sweating and sensory function in the corresponding area was complete. Sensation was partly restored four months after the operation. With regard to the persistence of sweating and the associated decrease in the electrical skin resistance in the small area shown in figure 3, it is possible that a small branch of the supraorbital nerve supplying this region was not severed at operation.

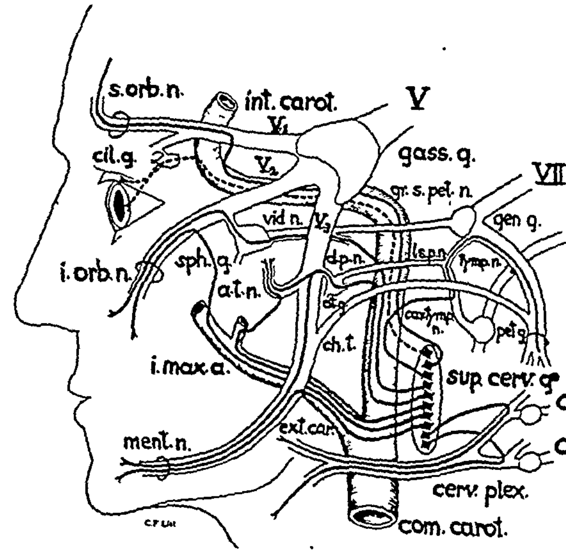

Fig. 5.—Schematic drawing illustrating the probable course of the sympathetic sweat fibers for the face (after List and Peet).

An apparent reason for the spontaneous occurrence of hyperhidrosis in the area of the supraorbital nerve could not be found. The patient never experienced pain, and a history of trauma to the nerve or of any infectious process in the region of it was lacking. The etiology and pathogenesis of the condition remain unknown. However, one might assume the presence of an irritative process affecting solely the autonomic fibers of a sensory nerve. Further investigation of electrical skin resistance in cases of neuralgia and circumscribed cutaneous conditions may reveal comparable abnormalities of autonomic innervation.

SUMMARY

A case of circumscribed hyperhidrosis over the left side of the forehead is described. After section of the supraorbital nerve the hyperhidrosis was abolished almost completely. The area of disturbed sweating was clearly outlined by measurement of the electrical skin resistance. The result of the operation confirms the conclusion of List and Peet on the course of sweat fibers to the forehead.

BACKGROUND TO CHEMOTHERAPY

In a recent issue the British Medical Bulletin[1] publishes, under the heading of "Background to Chemotherapy," a series of articles dealing with the historical and theoretic aspects of chemotherapy. E. M. Lourie believes that the term chemotherapy should be restricted in its meaning to the intention of its originator, Paul Ehrlich, applying only to the treatment of infections by chemical compounds. The aim of the investigator in chemotherapy, according to Schulemann, is to reach the parasite cells and to throw their function so irreversibly out of order that the parasite dies but the host remains as unharmed as possible. Ehrlich's greatest practical achievement was the introduction of arsphenamine (salvarsan) in 1910.

In 1935 Domagk announced p-sulfonamido-chrysoidin (prontosil) as an effective agent against infections with hemolytic streptococci, and Tréfouël, Tréfouël, Bovet and Nitti of the Institute Pasteur demonstrated that the part of the prontosil molecule which conferred staining properties was not essential to its therapeutic powers; these were equally efficient if the substance were abbreviated to p-amino-benzenesulfonamide (commonly known as sulfanilamide). These important contributions of the French workers to the subject of chemotherapy have not received sufficient recognition in relevant literature. The action of sulfanilamide and its successors was found to be mainly directed against hemolytic streptococci, Escherichia coli, meningococci and, to a less extent, gonococci. With the use of sulfapyridine pneumococci also were acted against, and with sulfathiazole and sulfadiazine the range of action widened still further to include that against staphylococci, though the latter are not as susceptible to any sulfonamide compound as they are to penicillin.

Sir Howard Florey points out that although the use of the word "antibiotic" to mean the actual chemical substances involved in bacterial antagonisms was only recently introduced by Waksman and his co-workers, the recognition of antagonisms between bacteria dates to an observation made by Pasteur and Joubert as early as 1877. They observed that if a culture of anthrax bacilli in urine was contaminated by organisms from the air, the anthrax bacilli were destroyed. By 1889, according to Florey, the phenomenon of bacterial antagonisms was well known and nearly all bacteriologists who worked on it at that time had in mind its use for therapeutic purposes. The first example of a mold yielding an antibiotic was recorded in 1896 by Gosio, when he obtained a crystalline substance from a penicillium in the course of his investigations on moldy maize. Although a large number of observations on antibiotics had been recorded from 1877 on, the observation which has had the greatest consequence was made in 1929, when Fleming noticed a mold which had accidentally contaminated one of his culture plates and which was causing the dissolution of staphylococci in its neighborhood. Chain, Florey and their co-workers at Oxford demonstrated that penicillin was a chemotherapeutic drug of great power, that is to say, it was of such low toxicity that it could, without producing any toxic signs, be injected by parenteral routes in amounts which would stop the growth of bacteria in all parts of the body. Results of clinical trial with penicillin were made known in 1943 by Florey and Florey. Two facts of special importance which emerged from the laboratory work at Oxford were (1) that extracted penicillin was fully active in the presence of pus and tissue-breakdown products and of large numbers of bacteria, all of which impaired the antibacterial action of all the sulfonamide drugs known at that time and (2) that even impure extracts were nontoxic to animals in concentrations hundreds of times greater than those required to inhibit the growth of bacteria and that with increased purity of extracts the toxicity became still less.

Among several antibiotic substances extracted by Waksman and his co-workers at Rutgers from the actinomycetes, one known as streptomycin has proved to be particularly valuable. It has little toxicity to animal tissues, and it stops the growth of many pathogenic organisms at high dilution and is active against some of the organisms not inhibited by penicillin. It has some effect against Mycobacterium tuberculosis. Its possible use for the treatment of tuberculosis is now being investigated. McIlwain in a contribution on "Analysis of Antibacterial Action" stresses that the first characteristic in the sulfonamide compounds to be connected with the differing abilities of the drugs to inhibit bacteria is the interacting ratios of the concentrations of the drugs and para-aminobenzoic acid. The second characteristic so correlated is the acidic-dissociation constant of the drugs As to the bacterial systems through which any one agent becomes effective and the organization of living systems in general, it appears that the "receptors" of earlier investigators are now usually regarded as enzyme systems.

The symposium contains an interesting contribution on the Nutrition of Bacteria by Sir Paul Fildes, on the Microbial Resistance to Chemotherapeutic Drugs by F. R. Selbie, on the Principles and Practice of Local Chemotherapy by L. P. Garrod and several other valuable papers on related subjects.

ARTIFICIAL TERMINATION OF PREGNANCY FOR ERYTHROBLASTOSIS FETALIS

The routine testing of pregnant women for the Rh factor and the search for antibodies in the serums of those Rh negative patients who have Rh positive husbands is resulting in the detection of literally hundreds of women who show sensitization prior to delivery. Most, of course, are multiparas, of whom some have previously given birth to a child affected by hemolytic disease of the newborn. Some are primigravidous women with or without a history of transfusion or abortion. In every case the question arises Shall this patient be allowed to await spontaneous labor at term, or shall the baby be delivered prematurely, by the induction of labor or by cesarean section? If labor is induced and results in a premature child without evidence of erythroblastosis, the physician wonders whether his intervention was justified. If a cesarean section is performed early and results in the birth of a child with hydrops fetalis, which dies a few minutes or hours later, then the physician knows that his operative intervention was not justified. Such results, occurring with increasing frequency, have led many, if not most, obstetricians to abandon the interruption of pregnancy in these cases. The dilemma is clearly due to the inability of the obstetrician to predict the outcome with any degree of accuracy.

In a recent report Page, Hunt and Lucia[1] indicated that the time at which appreciable amounts of either agglutinating or blocking antibodies appear during pregnancy is directly related to the fetal prognosis. By obtaining the first serum sample not later than the twenty-fourth week of pregnancy and assuming that the antibodies appeared halfway between the time of the last negative sample and the first positive one, the "appearance time" was dated in 49 cases. When only "traces" of antibodies could be detected, or isolated small amounts of anti-Rh or blocking antibodies were noted once but never confirmed, there were no instances of frank erythroblastosis, and all the babies survived. This would indicate that such traces or isolated small amounts may usually be ignored, regardless of when they appear during pregnancy. In the remaining cases appreciable amounts of either agglutinating or blocking antibodies were found and confirmed on examination of subsequent monthly samples. When the "appearance time" was less than ten weeks ante partum, all the infants were normal. When the antibodies appeared from ten to fourteen weeks before delivery 7 of 10 babies showed evidence of hemolytic disease; and while 3 of them succumbed, there were no instances of hydrops fetalis, the most severe form of erythroblastosis. Of the 12 cases in which the antibodies had existed for more than fourteen weeks, there were only 2 infants with erythroblastosis who survived and there were 7 cases of fatal hydrops fetalis. The exposure to persistent and appreciable amounts of either type of antibody for more than nine weeks in 22 mothers resulted in only 5 normal infants, 4 of whom were readily explained by the fact that they were Rh negative, the pregnancy probably having produced an anamnestic recall of previously existing antibodies.

From these preliminary data Page and his co-workers conclude that the artificial termination of pregnancy is probably unnecessary when Rh antibodies first appear less than ten weeks from term and probably useless when they appear more than fifteen weeks from the time selected for induction of labor. "The termination of pregnancy," they state, "by conservative means and the prompt transfusion of an anemic child at birth should result in a higher survival of infants only in that small group of mothers wherein antibodies appear for the first time ten to sixteen weeks before the estimated date of confinement. Beyond that period any attempt to reduce the exposure to ten weeks or less would probably result in the loss of the child from prematurity or from a combination of prematurity and erythroblastosis."

THE TAFT-SMITH-BALL-DONNELL MEDICAL CARE BILL

A revision of the Taft-Smith-Ball bill introduced this week is, in its general framework, similar to its predecessor. Senator Donnell has joined as a sponsor and two significant revisions are made.

In the original bill the Administrator of the National Health Agency was to be either a doctor of medicine with at least eight years of experience in the commissioned corps of the United States Public Health Service or a doctor of medicine licensed to practice medicine in one or more of the states, with at least five years of active practice and three years of experience in a responsible position in medical research, teaching or administration. The new bill will provide that the administrator must be a "doctor of medicine licensed to practice in one or more of the states and who is outstanding in the field of medicine."

Again, in the bill introduced in the Seventy-Ninth Congress, the United States Public Health Service, acting through the Surgeon General, was designated as the administrative agency on the federal level in relation to state programs to provide medical and hospital care for families and individuals of low income. This will be changed and there will be established in the pro-

ABSTRACT PERIODICALS

The British Medical Association began publication in January of two new periodicals entitled *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology*. These are an outgrowth of the *Bulletin of War Medicine* published during the war years and discontinued in 1946. The new periodicals do not attempt to abstract all the articles published in all the medical journals. A selection has been made of the periodicals considered worthy of study, now about 1,000, and from these are chosen for abstract the articles judged to be of use to medical readers. The abstracts are collected under specialized headings, such as Hygiene and Public Health, Physiology and Biochemistry, Pharmacology and Therapeutics and under other medical specialties and groups of diseases. The name of the abstracter is attached to each abstract. As was announced in THE JOURNAL last week a similar publication is contemplated to be published in English in the Netherlands. made in the mobilization of medical service in
emergencies. Five thousand questionnaires represen
a small percentage of the total number of physicians who remained in civilian practice. Dr. Edward L. Bortz of Philadelphia, chairman of the Committee on National Emergency Service, has appealed to every physician receiving the civilian questionnaire to respond promptly. The accuracy of the facts obtained and the soundness of the conclusions made by the study will be determined to a great degree by the cooperation which those receiving the questionnaire give the committee. The committee received excellent cooperation from the 50,616 former medical officers who were mailed questionnaires last December on their experience in military service. These are now being analyzed and studied. The facts obtained will be used as a basis for recommendations to be made by the committee to the House of Delegates in June. With the cooperation of the 5,000 physicians who are now receiving questionnaires on their civilian experience, the committee will be able to complete the total study of how the medical profession can best serve our population, civilian and military, in the event of a future national emergency. Every physician who receives one of these questionnaires has a professional and humanitarian duty to perform in completing it and returning it promptly. It is preferred that each sign his name, but if any one wishes to remain anonymous, he may do so. A broad representation of facts, experiences and opinions will add to the scientific value of the results.

posed National Health Agency an Office of Medical and Hospital Care Services to supervise the administration of state programs. The director of this agency will be a doctor of medicine licensed to practice medicine, who has had at least five years of active medical practice, and who is outstanding in the field of medicine.

The new measure will require, as did the earlier one, that the state agency to administer the contemplated program on a state level must be the state health agency after a specified number of years. This would seem to be an inconsistency, since the federal administrative functions will be removed from the public health agency. It had been suggested that each state be permitted to designate its own agency, without federal interference in the selection.

A new section will be added authorizing an annual appropriation of $10,000,000 for a cancer program, which will replace a section in the old bill proposing grants for general medical research. The Administrator of the National Health Agency will be directed to make a study of the organization and staffing of the agency and report to the Congress his recommendations, the study to include among other things the desirability of retaining or modifying the commissioned corps of the United States Public Health Service and the desirability of establishing an Office of Health and Medical Research as a constituent unit of the agency.

The revised bill, while an improved measure, requires additional consideration, and it is assumed that adequate hearings will be held at which suggestions for improvement may be made before action is taken on it by the Senate Committee on Labor and Public Welfare.

ABSTRACT PERIODICALS

The British Medical Association began publication in January of two new periodicals entitled *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics and Gynaecology*. These are an outgrowth of the *Bulletin of War Medicine* published during the war years and discontinued in 1946. The new periodicals do not attempt to abstract all the articles published in all the medical journals. A selection has been made of the periodicals considered worthy of study, now about 1,000, and from these are chosen for abstract the articles judged to be of use to medical readers. The abstracts are collected under specialized headings, such as Hygiene and Public Health, Physiology and Biochemistry, Pharmacology and Therapeutics and under other medical specialties and groups of diseases. The name of the abstracter is attached to each abstract. As was announced in The Journal last week a similar publication is contemplated to be published in English in the Netherlands. No doubt, as other nations of the world return to the routine of medical life that prevailed in the prewar years, there may be revivals of abstract periodicals in the German speaking and Slavic nations. In the United States there are available the Current Medical Literature department of The Journal of the American Medical Association, the abstract departments of the specialized journals and several periodicals devoted wholly to abstracts of medical literature. Important also is the extensive abstracting service known as the *International Abstract of Surgery*, which appears in *Surgery, Gynecology and Obstetrics*.

PHYSICIANS IN CIVILIAN PRACTICE DURING WAR

In the event of another war the provision of medical care for civilian populations might be just as vital to victory as care of the men in the armed forces. New methods of war strike at industrial areas. The medical profession is wisely attempting to prepare now the facts and recommendations needed for any such future emergency. Recently 5,000 questionnaires have been sent to physicians, selected at random, who were in civilian practice during the war just ended. On the basis of the answers to these questionnaires, sent out by the Committee on National Emergency Service of the American Medical Association, facts may be developed as to how the civilian population was served in World War II. The questionnaires also provide an opportunity for those who were responsible for civilian care in those years to indicate what changes should be made in the mobilization of medical service in future emergencies. Five thousand questionnaires represent a small percentage of the total number of physicians who remained in civilian practice. Dr. Edward L. Bortz of Philadelphia, chairman of the Committee on National Emergency Service, has appealed to every physician receiving the civilian questionnaire to respond promptly. The accuracy of the facts obtained and the soundness of the conclusions made by the study will be determined to a great degree by the cooperation which those receiving the questionnaire give the committee. The committee received excellent cooperation from the 50,616 former medical officers who were mailed questionnaires last December on their experience in military service. These are now being analyzed and studied. The facts obtained will be used as a basis for recommendations to be made by the committee to the House of Delegates in June. With the cooperation of the 5,000 physicians who are now receiving questionnaires on their civilian experience, the committee will be able to complete the total study of how the medical profession can best serve our population, civilian and military, in the event of a future national emergency. Every physician who receives one of these questionnaires has a professional and humanitarian duty to perform in completing it and returning it promptly. It is preferred that each sign his name, but if any one wishes to remain anonymous, he may do so. A broad representation of facts, experiences and opinions will add to the scientific value of the results.

FUNCTIONAL TESTS IN DIAGNOSIS OF CORONARY DISEASE

Functional tests have been devised to reveal latent coronary insufficiency. They have some applicability for three groups of patients: those with some disorder in the chest slightly suggestive of angina, those whose symptoms resemble those of angina but whose chest pain is mild or atypical, and, finally, patients with clearcut angina with or without previous myocardial infarction. A functional test should provoke pathologic changes in the coronary circulation and cause a relative disproportion between supply of blood and demand, and thereby elicit anginal pain or typical electrocardiographic changes or both. According to Biörck[1] of Stockholm there are at least three ways of functional testing. The oxygen saturation of the blood can be reduced either by giving a patient a gas mixture which is deficient in oxygen or by using a low pressure chamber; the patient can be exercised, which increases the cardiac demand for oxygen without reducing the supply, or the work of the heart can be increased by epinephrine, the latter being the most dangerous method. Biörck has used the anoxemia or, as he prefers to call it, the hypoxemia test, by means of a 10 per cent oxygen and 90 per cent nitrogen mixture breathed for twenty minutes—or less in case definite anginal pain develops. Immediately after finishing the test the patient is allowed to breathe 100 per cent oxygen for at least five minutes. Electrocardiograms are taken at suitable intervals. Such tests may produce unpleasant and even alarming reactions, Biörck says, and cannot be recommended for general use.

A TRIBUTE TO THE YOUNG PHYSICIAN

Since demobilization, many thousands of experienced physicians have returned from military service to practice in civil life. Remaining in the service to care for the sick and wounded in the peacetime army and in the armies of occupation in Germany and Japan are mostly recent graduates in medicine, many of whom received their professional training under the Army specialized training program. The Deputy Surgeon General of the Army, Brig. Gen. Raymond W. Bliss, who recently returned from an inspection of medical installations in the European theater, has reported on the overall excellence of the service provided by these young physicians in Germany, France and Italy. General Bliss pointed out that during the war the medical corps was more of a cross section of mature American medicine. Today he said the cross section is of recent graduates who have completed their internships and varying degrees of medical and surgical residencies. These young physicians, he said, are alert, well trained, energetic, careful of their examinations of patients and thoroughly interested in their work. Patient care is on a high level and compares favorably with the highest standards of American medical practice. Commanding generals of headquarters, without exception, expressed their appreciation of the quality of the medical officers in their commands. These encouraging words are a well merited tribute to the young physicians now serving this country; they are a tribute also to those who evolved our system of medical education and who maintain its standards.

FUNDAMENTAL REQUIREMENTS OF INSURANCE

Elsewhere in this issue appears a statement of the fundamental requirements for insurance by the director of the Bureau of Medical Economic Research of the American Medical Association. His article sets forth succinctly the points of basic importance in any insurance program. With these points in mind, the fundamental lack of soundness in a nationwide compulsory sickness insurance system in a government such as ours becomes apparent. (The federal Social Security Act does not cover every citizen nor does any other experiment in social insurance in the United States.) The power to include every citizen in any scheme of social insurance is an inherent attribute of sovereignty, although no social insurance system in the world actually covers every person. One hundred per cent full employment cannot be maintained in a free enterprise system but is theoretically possible in a totalitarian society. A nation which can compel every citizen to inclusion in a medical care program could equally compel every citizen to purchase shoes, hats, tobacco or any other item in common use in the nation. A compulsory system of sickness insurance invokes the power of the state to determine the contribution of each citizen, which is essentially a tax, and to determine the extent of the benefit received. In such a system a definite connection between the two scales need not exist. In an insurance plan the benefit must be definitely related to the premium. Social insurance is based on the power of the government to compel action. Thus it could violate all the fundamental requirements of insurance that are listed by Dickinson. The program depends on the power of government to meet deficits by other taxes without relationship to the actual cost of the insurance. Thus insurance and social insurance are two entirely different procedures. The American people have shown their confidence in insurance by their voluntary purchase of life insurance, motor car insurance, fire insurance and other forms in which the basic principles of insurance prevail. They can no doubt be persuaded or taught similarly to avail themselves of sound voluntary systems of insurance against the costs of hospitalization and sickness. If Americans want to maintain the free society by which our nation has grown to its present high estate they will abide by the time tested requirements of insurance in seeking protection against the hazards of sickness and they will avoid the blind faith that would be necessary to usher in a uniform system of compulsory sickness insurance in this country.

President Asks Continuance of Controls on Streptomycin

American made streptomycin is one of eight groups of items on which President Truman has asked Congress to continue controls beyond March 31. According to the Civilian Production Administration the request was made because of the growing importance of the drug in the national health program. A sudden rise in demand is expected if further clinical evaluation indicates that it is useful in the treatment of tuberculosis and other diseases. Dr. Paul A. Bunn, associate chief, Veterans Administration tuberculosis division, reports that streptomycin has been so successful in the treatment of advanced tuberculosis in seven veterans' hospitals that nineteen study units have been added. Of 50 veterans who had the deadly, military type, the meningitis type or a combination and would certainly have died, 27 are alive, Dr. Bunn reported. Of 91 veterans with the common pulmonary tuberculosis, all advanced, 77 per cent improved with the drug treatment and none got worse. No cases were completely cured. Studies have been conducted since last July.

Stand of Association Against Insurance Legislation Explained by Speaker

Dr. Henry Cook Macatee, president, Washington Health [illegible]y Administration, told the Washington Club here why [illegible] American Medical Association opposes proposed legislation [illegible] federal health insurance. He said the medical profession is not opposed to "socialized medicine" and cited various projects the profession has supported, such as milk pasteurization, vaccinations, community hospitals and other health measures designed for the public good. He declared that the Wagner-Murray-Dingell bill was opposed because it would hinder medical research, doctor-patient relationships and other liberties contributing to medical progress and simultaneously would fail to provide promised benefits. The bill would place medicine under control of bureaucracy, and the costs would be prohibitive.

Neurosyphilis on Decline Twenty-Five Years After Beginning of Malaria Treatment

Dr. Theodore C. Fong, head of the syphilis department in the medical-surgical hospital at St. Elizabeths Hospital, believes that neurosyphilis was on the decline when the twenty-fifth anniversary of the use of malaria to fight dementia paralytica was noted here. He stated his belief that the crusade against venereal disease, together with advances in chemotherapy, especially the use of penicillin, will further reduce hospital admissions for dementia paralytica and locomotor ataxia. Dr. William P. Herbst, president of the District of Columbia Social Hygiene Society, reports that the capital's venereal disease rate has been reduced by better diagnosis and treatment and improved public health programs. Major Gen. Norman T. Kirk, Surgeon General of the Army, declared the venereal disease rate among American troops had been exaggerated.

Study of Proposals to Create Federal Department of Health

Dr. George F. Zook, president of the American Council of Education, heads a committee appointed to study proposals to create a federal department of health, education and security. The committee has been sponsored by the council and by the National Social Welfare Assembly. Serving as co-chairman are Dr. Ernest L. Stebbins, Johns Hopkins University, and C. M. Bookman, executive vice president, Cincinnati Community Chest.

Cancer Survey to Be Conducted

Dr. Harold F. Dorn of the U. S. Public Health Service has been lent to the District health department to conduct a cancer survey. He will be assisted by ten medical students from local medical schools. Dr. Calvin T. Klopp, director of the Warwick Memorial Cancer Clinic at Garfield Hospital, announced that the clinic has been completely reorganized so that any patient having or suspected of having cancer can be accepted. Dr. John Rogers, research trainee at the National Cancer Institute, was assigned to the clinic for training. The institute announced the opening of a cancer clinic for children in Gallinger Hospital. Institute specialists report that tumors in children are more common than is realized.

Bill to End "Fly by Night" Training Schools for Practical Nurses

A bill to end "fly by night" training schools for practical nurses has been presented to District authorities for submission to Congress. It has the backing of the Undergraduate and Practical Nurses' Association, the Graduate Registered Nurses' Association, the Medical Society of the District of Columbia and the District board of health. Mrs. Elizabeth Earl, legislative chairman, Graduate Nurses, stated that "the bill will standardize education and training schedules of all practical nurse training schools so that graduates can fully meet the requirements for licensing."

Production of More Efficient Artificial Limbs

Major M. J. Fletcher, director of the Army Prosthetic Research Laboratory at Walter Reed Hospital, reports that more efficient artificial limbs than those now in general use by amputees are being produced. In the year since the laboratory was set up new appliances have been devised, some fitted for amputees. The advantages reported are great pressure, smoother operation and easier control, lightness and easier maintenance and appearance almost indistinguishable from that of natural limbs.

Veterans Administration Patients Without Service Connected Disability

Dr. Paul R. Hawley, medical chief, Veterans Administration, informed the House Committee on Veterans Affairs that 82.5 per cent of all patients in veterans' hospitals have no disability or illness connected with service in the armed forces. Dr. Hawley outlined the veterans' medical program and said that no veteran with a service connected illness has to wait a single day to get into a hospital for treatment. Plans are under way to build seventy-four new hospitals.

Distribution of Surplus Plasma

The American Red Cross is distributing 1,500,000 packages of plasma declared surplus by the armed forces at the end of the war, officials have announced. More than half has already been allocated to various states. Dr. G. Foard McGinnes, Red Cross vice chairman for health services, states that "this marks the first time in the history of medicine that enough plasma is readily available for normal and emergency needs in civilian medical practice."

Decrease in Illegal Drug Traffic But More Arrests

The enforcement division of the U. S. Treasury Department has reported a drop in the illegal drug traffic but an increase in arrests during 1946. The close of the war and the interruption of supply lines were credited with cutting the drug traffic. There were more than 3,000 arrests for narcotic and marihuana law violations in 1946 compared with about 2,000 in 1945.

Bethesda Becoming "Health Center of the World"

Bethesda, Md., home of the Naval Medical Center, the National Institute of Health, and the proposed site of atomic research facilities, a mental research institute and other facilities, is being publicized as living up to its historic namesake, the Biblical pool where the ill were healed. The town is called "Health Center of the World."

Medical Economics

FUNDAMENTAL REQUIREMENTS OF INSURANCE APPLIED TO VOLUNTARY PREPAYMENT MEDICAL CARE PLANS

FRANK G. DICKINSON, Ph.D.
Director, Bureau of Medical Economic Research
Chicago

The physician has a professional interest in the success of voluntary prepayment medical care plans because they demonstrate the determination of his profession to provide a sound method of budgeting the costs of better medical care. As a citizen of the community, he has an interest in their success because they offer the best way of solving, on a democratic basis, the difficult social and economic problems created by the irregularity in the family's need for the services of physicians. As these plans develop, the physician will come to look to such plans for a more or less substantial part of his income. He will want to be certain that they will be able to fulfil their obligations.

Successful voluntary prepayment medical care plans must follow the sound basic requirements of insurance—requirements which have been discovered and tested by generations of experience in other fields and which have endured to guide the medical profession in extending the benefits of medical service. Furthermore, not all economic risks are insurable.

Every physician should familiarize himself with the few basic requirements for the successful operation of any such insurance plan. He will want to discuss these requirements with his colleagues and with others in the community who are interested in making adequate medical care available at a reasonable cost. Finally, he will want to use his influence to make certain that the plan with which he is connected or which is being planned in his community meets these seven basic requirements:

1. *Laws of Mathematical Probability.*—All insurance is based on the ability to predict, with a high degree of accuracy, just how often a certain event may occur. The first essential requirement of health insurance, then, is that there shall exist laws of mathematical probability which apply. The laws of probability are well developed and will apply to health insurance if the other essential conditions of insurance actually are met.

2. *Insurable Interest.*—A second requirement of insurance is that the person must stand to lose financially by the occurrence of the event against which he wishes to be insured. Every one knows that one cannot buy a fire insurance policy on a building which one does not own. One cannot insure the life of a total stranger in whose welfare one has no personal interest. This requirement is known as that of insurable interest. Since any one subscribing to a health insurance plan can be assumed to be financially interested in the health of himself and his family, this requirement can be met.

3. *A Large Number of Independent Risks.*—A fire insurance company could not afford to concentrate its entire business in a single congested area of a city which might be wiped out by a single blaze. It is necessary that such a company spread its risks over a large number of individual buildings located over a wide area. In this way the company is risking the occurrence of a large number of separate fires rather than a single totally destructive one. By the same token, a prepaid medical service plan cannot afford to limit its membership to a group of employees or families working or living so close together that a single epidemic might cause a high percentage of the premium payers to require medical service at the same time. The third requirement, then, is that there shall be a large number of policyholders scattered over a wide enough area so that it is unlikely that any substantial percentage of persons will demand medical service at any one time.

4. *Importance of the Risk.*—Actuarially, it would be possible to predict the occurrence of, and to offer insurance against, becoming bald at the age of 35. Except in the occasional case of some one such as an actor, however, it is doubtful that any one would consider a risk of this kind sufficiently important to warrant paying the cost of operating an insurance business for such a purpose. Health, on the other hand, is important enough to every one to justify the payment of premiums sufficiently large to provide medical care and to defray the operating cost of the plan. This is true also in the case of prepayment plans which offer only surgical benefits, since a substantial number of the cases in which sickness proves an overwhelming burden on the patient's pocketbook involve surgical service.

5. *Uncertainty of Occurrence.*—It is not sound to attempt to use insurance to guard against something that is certain to occur. For instance, it would be unsound to attempt to use insurance to guard against the depreciation of a building. Buildings are certain to depreciate. If a policy against depreciation were offered, the premiums charged would have to be high enough to meet the total cost of depreciation plus the cost of operating the insurance company. For this reason, sound business practice has established the plan of setting aside a certain amount each year to meet depreciation costs, thus avoiding the necessity of paying the additional operating costs of an insurance business.

An all inclusive health insurance policy approaches this limitation of certainty. It is almost certain that any given family will need the services of a physician three or four times a year. Any attempt to cover these usual and minor expenses for medical care, then, actually violates this requirement of uncertainty of occurrence. Rarely does insurance meet the full amount of the loss in any kind or type of insurance. Since we are dealing with something that is almost certain to occur, the policyholder would be just "trading dollars" with the health insurance plan which covered all expenses. The premium in such cases must be large enough to cover the cost of the initial visits which the policyholder is almost certain to require each year—plus the cost of operating the plan—plus the necessary amount to build up a reserve to meet the occasional severe illness. Therefore the policyholder is actually paying more for these initial visits than he would pay if he dealt directly with his physician for these minor needs. In order to provide adequate funds to meet these needs, plus operating expenses, plus reserve for the occasional severe illness, the plan's premiums must be so high as to discourage widespread participation. If they are not, the time will come when the plan will have so exhausted its resources in meeting the costs of minor illnesses that it will be unable to meet the expenses of the major one. Compulsory sickness insurance systems in other countries specify a waiting period of three to fourteen days. Witness also the $25 deductible provision in the automobile collision insurance policy.

By way of illustration, there is no actuarial reason why a man of 85 should not buy a life insurance policy. However, it is not practical for him to do so because such a policy probably would cost something like $900 in a single premium plus the percentage of operating cost of the company in order to obtain a policy for $1,000. The reason is that at age 85 death is certainly so near that insurance against it is unsound economically.

6. *The Insurance Itself Must Not Immeasurably Increase the Risk.*—If there were no arson laws for the punishment of persons proved guilty of incendiarism, it is highly probable that fire insurance companies would be unable to operate. It would be too simple for a person to take out a fire insurance policy and then to set fire deliberately to the building in order to collect the insurance. In such a case the issuance of the insurance policy would have increased the risk of destruction of the building by fire, since the owner certainly would not have burned his property unless he had some hope of extra compensation.

We must examine this requirement carefully in considering plans for health insurance. Will a family which has a health insurance policy make greater demands on its physician than it would make if it did not have such a policy? Unlike the case of incendiarism, there are no laws to prevent persons from making unnecessary demands on their physician for his services. However, if the number of extra calls on a physician due to the issuance of the health insurance policy is increased to a degree which can be measured and predicted, then it still is possible to determine the probable cost of operation and feasible to issue such policies. If the increase cannot be measured and predicted, the risk cannot be insured. (It must be remembered that if the increase in risk on this basis made loss almost certain, it would violate requirement 5, even though it could be measured and predicted.)

7. The Risk Must Be Measurable.—This is by far the most important requirement of insurance. It means simply that it must be possible to determine in advance just how frequently losses are likely to occur, just how great those losses are likely to be in the aggregate and for each risk so that the correct premium can be determined. In health insurance it means that it must be possible to figure out in advance just how much the total doctor bill for each thousand insured persons or families is likely to be.

There are a number of clear examples of violations of this fundamental requirement. For instance, there were the mortgage guaranty companies which flourished in New York State in the 1920's. For one half of 1 per cent or more of the interest paid, they agreed to pay interest and principal of the mortgage if the borrower was unable to do so. Everything went well as long as times were good and a relatively few borrowers defaulted. In the 1930's, however, when the depression struck, borrowers defaulted in such great numbers that these insurers were unable to meet their obligations out of their reserves. The difficulty here was that it is impossible to predict when there will be a great depression or how many borrowers will default on their payments.

Another illustration of the violation of this requirement is the experience that life insurance companies had with the disability provisions which they issued in the 1920's. This special rider on life insurance policies provided for the payment of $10 monthly per thousand dollars of insurance in the event of disability. Disability usually was defined as the inability of the person to perform his duties. When widespread unemployment, financial bankruptcy and unproductive business operations came in the 1930's, great demands were made on this disability provision. Some of these demands were genuine because of sickness or worry. Undoubtedly, however, there was a large amount of malingering on the part of persons who found it more profitable to remain at home drawing benefits than to attempt to return to unprofitable business operations or nonexistent employment. The insurance companies lost heavily and ceased to write such policies.

Another example is unemployment compensation if viewed as insurance. It will be remembered that the late President Roosevelt always was very careful to refer to it as unemployment compensation rather than unemployment insurance. The fact is that it is not insurance because it violates this essential principle that the risk must be measurable. Who can measure how long the next protracted period of mass unemployment will be? Who knows when it will come? Who can tell how much prosperity will intervene during which period wage earners will be paying into the reserves of the fund? Since none of these things can be measured, it is impossible to tell what the total risk may be in the long run, and it is therefore impossible to tell how much reserve will have to be amassed to meet that risk.

This requirement that the risk must be measurable is highly important to the physician who is concerned with the success of prepayment medical care plans. It is not enough that the plan has completed one year, or five years, with a reserve fund on hand. It must be strong enough to weather a great depression during which the loss and expense ratios might rise rapidly even though the general health situation was favorable. Reserve funds developed in prosperous times will doubtless be needed to offset unpredictable increases in loss and expense ratios during depressions. For this reason the "pro rata" feature is excellent; it provides that the participating physicians must accept less than their approved fees if the income of the plan for the year is less than the amount of the total approved fees. This transfer of some of the risk, especially in a year of depression, from the plan to the participating physicians makes them underwriters and should make their plan a tower of strength during periods of unemployment. This feature would enable any plan to comply fully with this seventh essential requirement of insurance because, even though certain health risks may not be measurable or predictable, the plan is secure. Premiums need not be equal each year to the total approved fees of the participating physicians for services rendered members during that year. The physician is, in the language of the insurance world, a reinsurance underwriter. Without this feature a plan might be a house of cards instead of a tower of strength at the bottom of the business cycle. Although the "pro rata" feature may be hard on the doctor, it makes the plan stronger than it would be if it merely complied with the seven fundamental requirements of insurance. The stronger the plan, the better it is for the doctor.

The experience amassed by prepayment medical care plans since 1940 does not cover a sufficiently long period of time or a sufficiently broad section of the population during depression and prosperity to permit us to measure with accuracy the risk that might be involved in the event of a serious epidemic or a great depression. The "pro rata" feature enables our medical care plans to meet this essential requirement of sound insurance practice *now* without waiting to accumulate broad and detailed actuarial experience.

COMMENT

I have set forth the seven characteristics of an insurable economic risk. I believe that voluntary prepayment medical care plans, carefully designed and operated, comply with these requirements forged out of several centuries of insurance experience. The most serious mistake which doctors could make would be to claim too much for this great economic and social institution of a free society. As Marshall de Villars said when taking leave of Louis XIV, "May God defend me from my friends; I can defend myself from my enemies."

Medical Legislation

MEDICAL BILLS IN CONGRESS

Streptomycin

A bill introduced by Senator White, Maine, S. 445, at the request of the Federal Security Administrator, proposes to amend the Federal Food, Drug and Cosmetic Act of June 25, 1938, as amended, by providing for the certification of batches of drugs composed wholly or partly of any kind of streptomycin or any derivative thereof. Two other drugs are now certified by the Food and Drug Administration, insulin and penicillin.

Medical Department of the Army

Companion bills propose to revise the Medical Department of the Army, S. 504, introduced by Senator Gurney, South Dakota, and H. R. 1673, introduced by Representative Bolton, Ohio. Among other things, this legislation would establish in the Medical Department of the regular Army a Medical Service Corps to consist of a Pharmacy Section, a Medical Allied Science Section, an Optometry Section and such other sections as may be deemed necessary by the Secretary of War.

Federal Grants-in-Aid to State and Local Governments

A resolution introduced by Senator Morse, Oregon, S. 61, proposes to authorize a duly appointed subcommittee of the Committee on Labor and Public Welfare to make a study with respect to existing and proposed federal grants to state and local governments for welfare, education and health programs and to report to the Senate from time to time the results of its studies and investigations, together with such proposed legislation and other recommendations as it may deem desirable.

Medical Care for Dependent Members of Veterans' Families

A bill introduced by Senator Pepper, Florida, as S. 465, proposes that the dependent members of the family of a veteran of any war of the United States shall be furnished proper medical examination, medical care, treatment, hospitalization, dispensary, convalescent care necessary and reasonable after-care, welfare, nursing and such other services as may be necessary for the maintenance of good health and the prevention of illness, such service to be made available by the Administrator of Veterans' Affairs at hospitals, domiciliary institutions, outpatient dispensaries or stations, or such other facilities available to or contracted for by the administrator, if suitable accommodations or services are available. Such service will be rendered at a per diem or other reasonable cost to such dependents concerned.

Miscellaneous

A bill introduced by Representative Fellows, Maine, H. R. 1589, would provide that all the provisions of all laws administered by the Veterans Administration which extend benefits to any woman who served honorably as a nurse, chief nurse or superintendent of the Nurse Corps under contract with the United States for ninety days or more between April 21, 1898 and Feb. 2, 1901 be extended to any man who served honorably in any such capacity under contract with the United States for ninety days or more between such dates.

Representative D'Alesandro, Maryland, proposes by H. R. 1537 to authorize the erection of a United States Veterans Administration general **medical-surgical hospital facility at Baltimore.**

The Civil Service Act would be amended by a bill introduced by Senator Ellender, Louisiana, as S. 159, to provide that **no person shall be discriminated against** in any case because of his or her impaired hearing, in examination, appointment, reappointment, reinstatement, reemployment, promotion transfer, retransfer, demotion or removal, with respect to any position the duties of which, in the opinion of the head of the agency concerned, may be efficiently performed by a person with impaired hearing.

STATE LEGISLATION

Arkansas

Bill Introduced.—H. 43 and H. 87 propose to require each applicant for a **marriage license** to present a certificate from a duly licensed physician stating that the applicant has undergone a standard serologic test for syphilis and has been found free from syphilis in a communicable stage.

Bill Passed.—H. 18 passed the house January 22. It proposes to require every physician at the time of the first examination to take or cause to be taken a sample of the **blood of a pregnant woman** and submit the same to an approved laboratory for a standard serologic test for syphilis.

California

Bills Introduced.—A. 717, to amend the business and professions code, proposes to authorize the issuance of a **naturopathic physician's certificate** which would authorize the holder "to practice naturopathy, which includes physiotherapy, manual, mechanical and manipulative therapy, psychoanalysis, psychotherapy, electricity, nonnarcotic herbs, supplemental foods, vitamins, air, water, diet, massage, endocrinology, biochemistry, accident and occupational therapy and all other natural methods consistent with naturopathic science" A. 797, to amend the probate code, proposes that every person of sound mind over the age of 18 years may by will **dispose of the whole or any part of his or her body** to a teaching institution, university, college or legally licensed hospital, either for use as such institution, university, college or hospital may see fit or for use as expressly designated therein. S 353 proposes the enactment of a **hospital survey and construction** act requiring a statewide survey of hospital facilities and a program for the construction of needed additional facilities, as well as the establishment of an Advisory Hospital Council The survey would be administered by the State Department of Public Health, which would be appointed as the state agency to accept money received from the federal government for state assistance in either survey or construction programs

Connecticut

Bill Introduced.—H 146 proposes to authorize the state department of health to obtain **human blood from donors** or from agencies, to process it and to provide reserves of blood or blood derivatives in various parts of the state.

Massachusetts

Bills Introduced—H. 706 proposes that the College of Physicians and Surgeons shall **not register any new students** other than persons who have served in the armed force of the United States during World War II and been honorably discharged therefrom H. 947 proposes that every physician registered to practice medicine and surgery who obtained his medical degree from a medical school registered in the state at the time he was licensed **shall be allowed to practice** his profession in every public hospital in the state supported by public funds and be able to treat patients medically or surgically in such hospitals, and that the right to so practice shall not be denied because the physician is not a member of a private medical society or because of religion, nationality or race. H. 1132 proposes the enactment of a law providing for a voluntary system for the payment of hospital, surgical operation, sickness and bodily injury and maternity **benefits to employees.** H. 1619 proposes the enactment of a cash sickness compensation act. S 167, to amend the law relating to hospitals, proposes that hospitals, except those established by the commonwealth or any political subdivision thereof and those in which not less than one third of the patients are charity patients, **shall be liable in tort for damages** to patients resulting from acts of negligence of the agents or servants of the hospital The benefits of this proposal would not accrue to charity patients S. 169, to amend the **workmen's compensation act,** proposes that the record of any examination, diagnosis, prognosis or treatment of an employee shall not be furnished, nor shall any of the information contained therein be furnished or disclosed, to any employer or insurer by any doctor, physician, surgeon, nurse or other person unless the employee consents

Missouri

Bills Introduced.—H 63, to amend the prenatal examination law, proposes that the **examination of a pregnant woman** for the presence of syphilis shall be mandatory rather than just with the consent of the woman H 64, to amend the law relating to the **control of contagious diseases** among school children, proposes to authorize the school board to require that all children show proof of immunity against diphtheria and smallpox.

Nebraska

Bill Introduced.—Bill No. 160 proposes the enactment of a state hospital survey and construction act requiring **an inventory of existing hospitals** and a program for the construction of needed additional facilities The proposal would also provide for compliance with the requirements of the federal hospital survey and construction act and regulations thereunder.

New Mexico

Bills Introduced.—S. 12 proposes the enactment of a state hospital survey and construction act requiring **a survey of existing hospitals** and a program for the construction of needed additional facilities. The proposal also provides for compliance with the requirements of the federal hospital survey and construction act and regulations thereunder. S. 21, to amend the food and drug act, proposes that **drugs to be sold at retail** and containing any quantity of aminopyrine, barbituric acid, cinchophen, dinitrophenol, sulfanilamide or their derivatives shall be subject to certain labeling provisions unless sold on a written prescription signed by a member of the medical, dental or veterinary profession licensed by law to administer such drug S 51 proposes **to define a clinic** as an establishment where patients are admitted for special study and treatment by a group of physicians practicing medicine together and proposes further that no person or group of persons shall use the word clinic in connection with any establishment or office which does not come within such definition S. 52 proposes to require all persons licensed to practice any of the healing arts to clearly **designate the school of medicine** or practice which such person is licensed to engage in and further provides that failure to comply with such restriction would constitute unprofessional conduct. S. 53 proposes to authorize the use of the **injunctive process** to restrain the illegal practice of medicine or the healing arts.

New York

Bills Introduced.—A. 493 proposes the enactment of a comprehensive statewide system **of health insurance.** A. 661, to amend **the medical practice act,** proposes that such act shall not apply to a corporation organized under the insurance law and employing duly licensed physicians or entering into contracts with duly licensed physicians, or with partnerships or groups of duly licensed physicians, to practice medicine on its behalf for persons insured under its contracts or policies A 662, to amend the section of **the medical practice act** setting forth grounds for the revocation of a license, proposes that the prohibition against advertising under a false or assumed name shall not apply to persons constituting a partnership or group of physicians who have an agreement with a nonprofit corporation created under the insurance law to provide medical care for insured persons of such corporation. A. 663, to amend the section of **the medical practice act** relating to the revocation of a license, proposes that nothing in the act shall prohibit physicians from practicing medicine as partners or in groups nor from pooling fees and monies received, either by the partnerships or groups or by the individual members thereof, for professional services furnished by any individual physician, member or employee of such partnership or group, nor shall the physicians constituting the partnerships or groups be prohibited from sharing, dividing or apportioning the fees and monies received by them or by the partnership or group in accordance with a partnership or other agreement.

Pennsylvania

Bill Introduced—S. 43 proposes that it shall be unlawful for any doctor, hospital, nurse or other person or persons practicing medicine or affiliated with the medical profession to perform **blood transfusions** without first having ascertained by a Wassemann test that the blood of the donor is free from any venereal disease.

Utah

Bills Introduced—H 88 and S 130 propose to authorize the issuing of licenses to practice as **a naturopathic physician** without the use of drugs and surgery or as a naturopathic physician and surgeon in accordance with the tenets of a professional school of naturopathy recognized by the department of registration, etc Naturopathy is not defined by the proposal S. 104 proposes an act to require the licensing, inspecting and regulating of hospitals and the appointment of a **hospital advisory council.**

Coming Medical Meetings

American Association for the Study of Goiter, Atlanta, Ga, April 3 5 Dr Thomas C Davison, 478 Peachtree St, N. E, Atlanta 3. Secretary

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, New York, February 27. Dr. Norman N. Smith, 291 Whitney Ave, New Haven 11, Secretary.

Central Surgical Association, Chicago, Feb. 20 22. Dr. Walter G. Maddock, 250 East Superior St., Chicago, Secretary.

Chicago Medical Society Annual Clinical Conference, Chicago, March 4-7. Dr. Willard O. Thompson, 30 N. Michigan Blvd, Chicago 2, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 17-20. Dr. Glenn D. Earlson, 1133 Medical Arts Bldg., Dallas, Secretary

Michigan Postgraduate Clinical Conference, Detroit, Book Cadillac Hotel, March 12 14 Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Missouri State Medical Association, Kansas City, March 30 April 2 Mr. Thomas R. O'Brien, 634 N. Grand Blvd, St. Louis 3, Executive Secretary.

New Orleans Graduate Medical Assembly, New Orleans, Feb. 24 27. Dr. Max M. Green, 1430 Tulane Avenue, New Orleans 13, Secretary.

Pacific Coast Surgical Association, Seattle, Feb. 17-18; Victoria, B. C., Feb. 19-21. Dr. F. L. Reichert, Stanford University Hospital, San Francisco, Secretary.

Southwest Allergy Forum, Shreveport, La., March 31-April 1. Dr. Sim Hulsey, 505 Medical Arts Bldg, Fort Worth, Texas, Secretary.

Tennessee State Medical Association, Memphis, April 8 10. Dr. W. M. Hardy, 706 Church St, Nashville 3, Secretary.

GOVERNMENT SERVICES

ARMY

CELEBRATION OF ARMY WEEK

The War Department announces that Army Week will be observed for the first time April 6-12. The traditional Army Day celebration on April 7 will be held as usual and sponsored by the Military Order of the World Wars. The purpose of Army Week is not only to honor America's soldiers but to explain to the public the need for a well trained, efficient army of volunteers to discharge its duties as this country joins all United Nations in building permanent world peace; and to bring the people and the Army closer together in our national community. The theme is "A Strong America Is A Peaceful America." The War Department will conduct activities during Army Week in many cities and towns of the country. Ground forces and Air Forces will put on exhibits and demonstrations. Army posts and installations and National Guard armories will have "open house" on certain days. Many civic and other organizations will join in the celebration.

SOLDIERS' CHRISTMAS MAIL LOST AT SEA

About 2,800 sacks of Christmas mail for military personnel in Korea were lost at sea, the Adjutant General has announced. The sacks contained parcel post, magazines and newspapers only, no letter mail being lost. This mail was aboard the *Lakeland Victory*, which left San Francisco on November 27. The ship encountered a hurricane about 1,700 miles from Korea, sustaining severe damage and loss of the mail. Post offices will accept claims covering the loss or damage of insured parcels mailed to military personnel overseas after four months have elapsed from the date of mailing. Persons whose packages may have been affected may apply to their local postmasters for further information after the four month waiting period has elapsed.

ESTABLISH VENEREAL DISEASE CONTROL COUNCIL

The War Department has announced the establishment of a Venereal Disease Control Council for the purpose of insuring that all possible control measures are employed to reduce venereal disease in the Army. The council will meet each month to consider such problems, to develop standard educational and control measures and to review control procedures adopted in the field. The council is authorized to take immediate corrective action when reports indicate unsatisfactory conditions which are beyond the control of the local or army commander and to establish policies for the reduction and control of venereal disease based on research, surveys and field experience. The members of the new council are Major Gen. Willard S. Paul, chairman; Major Gen. Norman T. Kirk, the Surgeon General; Major Gen. Floyd L. Parks, chief, Public Relations Division; Major Gen. Luther D. Miller, chief of Army Chaplains; Brig. Gen. Russel B. Reynolds, chief, Special Services Division; Brig. Gen. B. M. Bryan, Provost Marshal General, and the recorder, Lieut. Col. John J. Easton. Additional members, representatives of the Secretary of War, Army Ground Forces and Army Air Forces, were to be named early in January.

As previously announced, the Army sent sixteen selected medical officers to attend classes in venereology at the University of Pennsylvania for two months, after which they will return to their stations and be followed by another class of selected medical officers. Such courses have become necessary, General Kirk said, to replace the specialists being separated from the service. While these courses will not produce specialists in venereal disease management, General Kirk said, this is a step in the right direction. The courses are being conducted by Dr. John H. Stokes, professor of dermatology-syphilology in the Graduate School of Medicine at the University of Pennsylvania.

ARMY AWARDS AND COMMENDATIONS

Colonel Albert W. Greenwell

The Legion of Merit was recently awarded to Col. Albert W. Greenwell, M. C., U. S. Army, of West Point, N. Y. The citation stated that as commanding officer, Regional Hospital, Fort Jay, New York, from July 1943 to June 1945, Colonel Greenwell rendered outstanding service. When this installation, originally a post hospital, was designated as a regional hospital, he speedily and effectively reorganized it to function as such without interruption of any of the regular services. He put into effect policies and procedures for expediting the processing of hospital cases without lessening the thoroughness of professional care and developed a comprehensive plan for emergency hospital service. Dr. Greenwell graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1916 and entered the service Aug. 28, 1917.

Colonel William P. Corr

The Legion of Merit was recently awarded to Colonel William P. Corr, M. C., A. U. S., of Riverside, Calif. The citation read as follows: "For meritorious service at Dibble General Hospital, Menlo Park, Calif., from October 1943 to June 1945. As Chief of the Professional services he organized this section on a high plane. He displayed at all times a wide knowledge of all phases of internal medicine, quiet yet forceful leadership and high ideals of the practice of medicine." As interim commanding officer of the hospital when near its peak load, he demonstrated administrative ability as well, and maintained the hospital in splendid condition. Dr. Corr graduated from Rush Medical College in 1924 and entered the service April 16, 1941.

Colonel Robert Skelton

The Legion of Merit has been awarded to Col. Robert Skelton, M. C., U. S. Army, the citation explaining that Colonel Skelton displayed outstanding ability as commanding officer, San Francisco Medical Depot, from December 1941 to August 1945, in solving the numerous problems of storage and distribution of medical supplies. His exceptional achievements contributed materially to the maintenance of a high standard of efficiency in depot operations and medical supply activities. Dr. Skelton graduated from the University of Pennsylvania Medical School in 1908 and entered the military service Feb. 1, 1911.

Colonel Paul A. Campbell

The Legion of Merit was recently awarded to Col. Paul A. Campbell, Chicago. The citation read as follows: "As Director of Research, Army Air Forces School of Aviation Medicine, from May 1942 to October 1945, Colonel Campbell directed a research program which provided solutions to hundreds of medical problems associated with aviation. His outstanding professional ability and extraordinary achievements reflect great credit on himself and the armed forces of the United States." Dr. Campbell graduated from Rush Medical College in 1928 and entered the service Nov. 29, 1940.

Colonel John C. Woodland

The Legion of Merit was recently awarded to Col. John C. Woodland, M. C., now of San Antonio, Texas. Colonel Woodland performed exceptionally meritorious services as chief of medical service and commanding officer, Brooke General Hospital, from December 1941 to March 1946. The citation emphasized his outstanding leadership and professional ability as reflected in the fine medical service provided by the hospital. Extensive research carried out under his supervision resulted in important discoveries in the field of virus and rickettsial diseases. Dr. Woodland graduated from the University of Maryland School of Medicine in 1915 and entered the service Feb. 25, 1918.

Lieutenant Colonel Raymond K. Farnham

The Legion of Merit was recently awarded to Lieut Col Raymond K Farnham of Scarsdale, N Y, for outstanding service as chief, disposition and retirement branch physical standards division, Office of the Surgeon General, from January 1944 to October 1945 The citation emphasized his exceptional skill and judgment in the development and compilation of the Medical Section of TM 12-245, a manual procedure for members of army retiring boards to follow in the consideration of officer personnel brought before them This officer, by his knowledge of medicine and surgery and his comprehensive understanding of the regulations, statutes and public laws governing the retirement of officer personnel gave expert advice and indoctrination to members of retiring boards throughout the United States as well as to high officials in the War Department members of Congress and officers being considered for retirement Dr Farnham graduated from the University of Vermont College of Medicine, Burlington in 1926 and entered the service May 6, 1942

Lieutenant Colonel William Leigh Cook Jr.

The Legion of Merit was recently awarded to Lieut Col Leigh Cook Jr, M C, A U S, of Alexandria, Va The citation states that, while serving as assistant director and later as director, Occupational Health Division, Office of the Surgeon General, from October 1942 to September 1945, he contributed immeasurably to the high standards characteristic of the industrial medical program in the Army He was a prime figure in establishing a successful occupational health program in the arsenals and industrial plants operated by the United States Army Through his unusual ability, industry and loyal devotion to duty he promoted a program to increase the health and efficiency of over 900 000 vital war workers Dr Cook graduated from Columbia University College of Physicians and Surgeons, New York, in 1934 and entered the service May 7, 1942

Lieutenant Colonel Walter E. Barton

The Legion of Merit was recently awarded to Lieut Col Walter E Barton, Worcester, Mass The citation read as follows "He served in various assignments in the office of the Surgeon General, Washington, D C, from April 1943 to June 1945 and was largely responsible for the organization and early development of the Reconditioning Program for convalescent army patients His specific services in shaping the doctrine and policy of the four interrelated services of occupational therapy, rehabilitation of the war blind and deafened, general reconditioning and reconditioning of neuropsychiatric patients were instrumental in furthering the standard of professional medical care and reflect the highest credit on himself and the Army Medical Corps" Dr Barton graduated from the University of Illinois College of Medicine in 1931 and entered the service Sept 10, 1942

Lieutenant Colonel Leonard B. Barnard

The Legion of Merit has been awarded to Lieut Col Leonard B Barnard, M C, A U S, of Oakland, Calif, for performing exceptionally meritorious services as assistant chief and later as chief of the orthopedic section of the surgical service, Woodrow Wilson General Hospital Staunton, Va, from March 1943 to February 1946 The citation stressed Colonel Barnard's outstanding professional skill in performing difficult operations, his effective training and supervision of his subordinates, and the consideration he showed for the hundreds of battle casualties under his care, which were largely responsible for the well-being and high morale among the patients and staff in the installation Dr Barnard graduated from Stanford University in 1927 and entered military service on Jan 11, 1943

Lieutenant Colonel Thomas Hale Ham

The Legion of Merit has been awarded to Lieut Col Thomas H Ham M C, A U S, of Boston The citation called attention to the breadth of scientific attainment displayed by Dr Ham as a member of the Medical Division Office, Chief of Chemical Warfare Service, from September 1943 to January 1946 His loyal devotion to duty and expert professional abilities contributed immeasurably to the successful achievement of the wartime mission of the Chemical Warfare Service Dr Ham graduated from Cornell University Medical College in 1931 and entered into the military service on Sept 4, 1943

Major Samuel P. Harbison

The Legion of Merit has been awarded to Major later Lieut Col, Samuel P Harbison M C, A U S, of Pittsburgh who served as chief, general surgery, 21st General Hospital in Africa, Italy and France from May 1943 to April 1945 The citation called attention to his unflagging energy, precise skill and keen scientific interest which enabled him to improvise equipment and improve technics with the result that many wounded personnel were saved from death or impairment Dr Harbison graduated from Cornell University Medical College in 1936 and entered the military service in January 1942

Major Manfred Guttmacher

The Legion of Merit was recently awarded to Major Manfred Guttmacher M C, A U S, of Baltimore, who as supervisor, Neuropsychiatry Consultants Division, Surgeon General's Office, from August 1944 to November 1945 rendered services of great value in preventive psychiatry and in the salvage of manpower The success of the army psychiatric work program was stated in the citation to have reflected his outstanding professional skill, clinical ability and sound judgment Dr Guttmacher graduated from Johns Hopkins University School of Medicine, Baltimore, in 1923 and entered the service Sept 30, 1942

Major Russell H. Barnes

The Bronze Star Medal was recently awarded to Major Russell H Barnes, M C, A U S, of Mansfield, Ohio The citation stated that as flight surgeon of the 320th Bombardment Group (M) and the 301st Bombardment Group (H) in North Africa Major Barnes performed meritorious service from November 1942 to May 1943, exhibiting outstanding professional knowledge sound judgment and unusual energy in rendering invaluable service although handicapped by physical suffering Dr Barnes graduated from the Hahnemann Medical College of Philadelphia in 1933 and entered the military service April 28, 1941

Major William J. Cromartie

The Legion of Merit has been awarded to Major William J Cromartie, M C, A U S, of McKinney, Texas, formerly of Nashville, Tenn, for performing exceptionally meritorious service as senior medical member of an intelligence mission in the European Theater of Operations from August 1944 to September 1945 The complete success of the mission, often under enemy fire, was attributed in the citation largely to his aggressive leadership, organizational ability, sound judgment and courage Dr Cromartie graduated from Emory University Medical School in 1937 and entered the military service Aug 11, 1942

Captain Charles W. Asbury

The Bronze Star Medal was recently awarded to Capt Charles W Asbury, M C, A U S, of Hamilton, Ohio, for meritorious achievement in connection with military operations from Feb 2, 1944 to June 8 1945 and in recognition of research work in the treatment of resistant dermatoses of the Southwest Pacific Area Dr Asbury graduated from the University of Cincinnati College of Medicine in 1942 and entered the service July 15, 1943

CORRECTIONS

Date of Entry into Service—The date of entry into the service of Lieut Col Harold R Hennessy as published in The Journal, February 1, page 330, should have been Nov 1, 1940

Award to Captain Saul Steinberg (0483911)—The award of the Army Commendation Ribbon to Capt Saul Steinberg, M C, A U S published in The Journal, January 4, page 47, was to Capt Saul Steinberg of Boston and not to Capt Saul Steinberg of Norristown Pa Captain Steinberg of Boston graduated from St Louis College of Physicians and Surgeons in 1926, he has been with the Boston Health Department since 1932 and in private practice in Boston since 1926 He entered the service in 1942 and was recently awarded also a Certificate of Commendation by the commanding general, Army Service Forces, 9th Service Command, War Department Personnel Center, Camp Beale, California, 'for strict attention to duty and performing his job in a superior manner as medical inspector from the period July 15 1945 to Feb 25, 1946

NAVY

SCHOOL OF AVIATION MEDICINE AND RESEARCH

Although the Naval School of Aviation Medicine has actually been in existence since 1939 and has trained about 1,400 doctors as flight surgeons and aviation medical examiners, it had never been officially designated as an activity until last October 15, when the Secretary of the Navy established the U. S. Naval School of Aviation Medicine and Research at the Naval Air Station, Pensacola, Fla. The school will continue to train young medical officers in aviation medicine and will continue its work in aviation medicine and research. Capt. Bruce V. Leamer (MC), U.S.N., has been named officer in charge.

LECTURE AT NAVAL MEDICAL CENTER

The fifth in a series of guest lectures at the Naval Medical Center, Bethesda, Md. sponsored by the Naval Medical School, was presented January 31 by Dr. Edward A. Strecker, chairman, Psychiatry Department, University of Pennsylvania Medical School, Philadelphia, on "Emotional Immaturity." Dr. Strecker is also consultant to the Surgeons General of the Army and Navy and special adviser to the Secretary of War. A cordial invitation to these lectures is extended to all physicians and medical officers in the District of Columbia and Montgomery County.

NEW ASSIGNMENTS

Rear Admiral Clarence J. Brown has been assigned as general inspector of the Medical Department and chief of the Research Division, succeeding Rear Admiral John Harper, who will become District Medical Officer for the 13th Naval District, with headquarters at Seattle.

Capt. Eric G. Hakansson has been appointed chief of the Research Division in the Bureau of Medicine and Surgery and will continue to be commanding officer of the Naval Medical Research Institute, Bethesda, Md.

Rear Admiral Carlton L. Andrus has been appointed Medical Officer in Command of the U. S. Naval Medical Center, Guam.

Rear Admiral John C. Adams formerly assistant chief of the Bureau of Aviation Medicine and Medical Military Specialties, has been appointed medical officer for the 5th Naval District, Norfolk, Va.

VETERANS ADMINISTRATION

HOSPITALS IN MEMPHIS

The management of the two veterans' hospitals in Memphis, Tenn., the Kennedy and the smaller hospital on Lamar Avenue, has been consolidated and Dr. Hugh L. Prather has been assigned as manager. Dr. Horace C. Dodge, formerly manager of the Lamar Avenue hospital, is reported to have retired at the beginning of the year after many years of service with the Veterans Administration.

WOMEN WAR VETERANS

Women veterans are entitled to the same medical care as male veterans, and in addition they may receive hospitalization for non-service connected disabilities in civil hospitals when government facilities are not available. Under present laws male veterans cannot secure hospitalization in private hospitals or treatment by private doctors at government expense for non-service connected ailments. This additional benefit is given women veterans as a result of an executive order issued in 1933, when only a few women veterans of World War I were eligible for Veterans Administration medical care. It was thought then to be more economical to authorize treatment and hospitalization for them from private physicians and in private hospitals than to construct special facilities in VA hospitals.

There were 1,339 women war veterans who were patients in VA hospitals, or in other hospitals under contract to VA on November 30, 1946, and in addition there were 212 women patients in VA homes. Of the total, 890 were veterans of World War II and the remainder veterans of World War I. The potential load of women war veterans is estimated at 350,000. The Veterans Administration has on its pension and compensation rolls at present 14,989 women veterans, of whom 1,456 are non-service connected.

PERSONAL

Dr. Harold F. Stolz, formerly of Saginaw, Mich., and Albuquerque, N. M., has assumed his duties in the department of medicine and surgery at the Veterans Administration Facility, Tucson, Ariz. From 1942 to 1945 he served as associate physician, cardiorespiratory diseases, Henry Ford Hospital, Detroit.

PUBLIC HEALTH SERVICE

PUBLIC HEALTH NURSING WEEK

A tribute will be paid to the services of the public health nurses of America in the observance of Public Health Nursing Week, April 20-26. The observance aims to spread the message that public health nursing services are for everybody and are not limited to those in lower income brackets; to encourage more nurses to enter the field of public health nursing; to interest more high school and college girls in choosing public health nursing as a career; to help relieve pressure on hospitals by calling attention to the fact that part time professional nursing care is available to people at home; to stimulate the development of organized health services in all areas of the United States, and to inform the people of the broad scope of the work done by the public health nursing services.

More than 20,000 public health nurses are employed in this country by local, state and national agencies. They work for health departments, boards of education and other official agencies and for nonofficial organizations such as tuberculosis associations, insurance companies, industries and visiting nurse associations. There is today one public health nurse to every 6,500 persons in the country. The U. S. Public Health Service in its announcement states that the country needs one public health nurse to each 2,000 of the population in order to render a complete public health nursing service, including bedside nursing in the home. This would require about 45,000 more than is now employed, based on the 1940 census.

Additional information may be secured from the Office of Health Information, Division of Public Health Methods, U. S. Public Health Service, 19th and Constitution Avenue N.W., Washington 25, D. C.

TEMPORARY ASSIGNMENT IN BOLIVIA

Senior Sanitary Engineer John J. Bloomfield, assistant chief, Industrial Hygiene Division, U. S. Public Health Service, has been assigned as special consultant to the Inter-American Affairs labor inspection and control program in Bolivia. He will remain there for two months to assist in the formulation of codes to establish healthful working conditions in industry and in the clarifying of occupational disease compensation laws. The institute, at the request of the Bolivian government, is setting up a program to improve the economic status of workers, particularly miners. Mr. Bloomfield will work with the institute's field party, which has been in Bolivia since 1945. He has been with the Public Health Service since 1923, and for thirteen years he pioneered in investigations of health hazards in industrial work.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education and public health.)

COLORADO

State Society Continues Annual Postgraduate Clinics.—The twelfth annual Midwinter Postgraduate Clinics of the Colorado State Medical Society will be held February 18-21 in Denver at the Shirley-Savoy Hotel. The clinics were suspended during the war years 1943-1945 and were revived in 1946. The first evening of the clinics proper is being given over to a nonscientific program featuring modern developments in the the problems of public relations of organized medicine. An innovation this year will be the technical exhibits.

FLORIDA

Personal.—Dr. Frank V. Chappell, Tampa, director of the Hillsborough County health department, was elected president of the Florida Public Health Association at its recent annual meeting. He succeeds Dr. George A. Dame, Fernandina.

Plane to Spray DDT.—At the request of the citizens of Fort Meyers the Army Air Forces sent a cargo plane fitted with DDT spray dispersal equipment to that area on January 25 to prevent fly breeding, after large numbers of dead fish were deposited by the tides on the beaches and in swamps. The War Department stated that the death of the fish was attributed to a minute sea organism. The plane was to spray the swamp area with a 20 per cent DDT solution in oil, and care was taken in the amount used in order to prevent injury to any form of wildlife.

GEORGIA

New Surgical Pavilion.—A new surgical pavilion in the Whitehead Memorial Room in Emory University Hospital, Atlanta, was dedicated recently. The pavilion was established by Mrs. Letitia P. Evans, Hot Springs, Va., mother of the late Conkey P. Whitehead, Atlanta. The dedicatory address was given by Dr. Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore.

School for Food Handlers.—Georgia established an educational program for food handlers, restaurant owners and operators, whereby three day food seminars were held last year at Atlanta, Savannah, Augusta, Columbus, Brunswick, Thomasville, LaGrange, Milledgeville, Hinesville, St. Simons and Jessup. There were 16,667 food handlers in attendance. According to the state health department numerous outbreaks of so-called food poisoning have occurred in Georgia as well as in some other states. The U. S. Public Health Service with mobile laboratories is said to have examined 50,000 utensils from 5,400 eating places in 156 American cities and found only 28 per cent free from dangerous numbers of bacteria. One bacteriologist, it is said, examined 54 samples of dish water from typical restaurants and found greater contamination than exists in the average sewer. The federal health agency warns that the amount of disease spread in restaurants is increasing.

ILLINOIS

Resolution of County Society.—The Adams County Medical Society has disapproved the present administration policies of the Blessing Hospital in Quincy, particularly as they are said to apply to the infringement on the private practice of medicine. The society in its resolution pointed out that plans are being made by this hospital to employ full time medical specialists on a salary basis and to sell their services to the patients in the hospital as well as to the general public.

Chicago

Industrial Tuberculosis Survey.—The Tuberculosis Institute of Chicago and Cook County reported February 1 that 13 active cases of tuberculosis and 77 suspected cases were disclosed by recent chest examinations of 5,298 employees in a Chicago manufacturing plant. Dr. Earl E. Kleinschmidt, director of the institute, said that none of the persons found to be infected were aware of the disease.

Hospital Staff Honors Colleague.—A bronze plaque honoring the long service of Dr. Mark T. Goldstine, a member of Wesley Memorial Hospital staff since 1902, was unveiled January 25 at ceremonies at the hospital. He is professor emeritus of gynecology and obstetrics at Northwestern University Medical School and chairman emeritus of the same department at the hospital as well as director of the Davella Mills Foundation Cancer Clinic.

Personal.—Dr. Camillo E. Volini has been appointed superintendent of clinics for the Municipal Tuberculosis Sanitarium, succeeding the late Dr. Edward P. Troy. Dr. Volini has been on the sanitarium staff for many years and since 1940 has been director of field collapse therapy.——Dr. A. C. Ivy, vice president, University of Illinois School of Medicine, Chicago, left early in January for Nuremberg, Germany, to serve as an expert witness and adviser at the trials of Nazi doctors charged with crimes of a medical nature and returned to Chicago, January 28.——Dr. William F. Petersen, University of Illinois College of Medicine, has been appointed director of the newly created department of clinical research at St. Luke's Hospital. ——Dr. John I. Perl, who for several years has been interested in painting as a hobby, has an exhibit at 111 East Delaware Street, which will continue until February 16.

The Third Annual Clinical Conference.—The Chicago Medical Society will hold its third annual clinical conference March 4-7 at the Palmer House. This intensive postgraduate course for the general practitioner will be presented by well known speakers, many from various cities in the United States. Among the subjects included in the morning and afternoon lectures, beginning at 8:30 and 2 o'clock respectively, are the surgical treatment of prostatic disease, causes and treatment of exophthalmos, diagnosis and treatment of the more common types of industrial dermatitis, surgical problems in diabetes mellitus, carcinoma of the uterus, chronic brucellosis, functional disorders of digestion, psychology and the general practitioner and psychosomatic gynecology. In addition there will be three panel discussions, a clinicopathologic conference and round table discussions at each luncheon.

INDIANA

Scholarships for Rural Medicine.—The Indiana State Medical Association is offering six or more scholarships each year for young men and women who wish to study medicine and practice in Indiana. Students who accept the scholarships must agree to be available for private practice in those counties "in which, in the opinion of the committee, medical service is most urgently needed." Principal cost of the scholarships will be borne out of funds appropriated by the council of the association. The scholarship committee is also authorized to accept donations from other sources. The medical association hopes thus to help meet the shortage of physicians in rural areas of the state. Dr. Alfred Ellison, South Bend, is chairman of the medical association council.

KANSAS

Health Officers' Conference.—The Kansas Local Health Officers' Conference was held January 9-10 in Lawrence, Dr. W. Fred Mayes, Topeka, director of local health administration, Kansas State Board of Health, presiding. The afternoon program was devoted to a discussion of the relationship of state consultant nurses to the local health departments, evaluation of nursing personnel and orientation of new nurses.

MASSACHUSETTS

Personal.—Dr. Hugo Muench, former member of the International Health division of the Rockefeller Foundation, and professor of biostatistics at Harvard University School of Public Health, has been appointed head of the department of biostatistics. He is also assistant dean.

Epidemic Among Infants.—Eight infants stricken with diarrhea have died at Cambridge City Hospital in an outbreak of 23 cases reported between December 4 and January 1. Of that number 7 were in Cahill House and 16 in the children's ward of the main building. All babies affected were under 10 months of age, according to Dr. George B. Foster, medical director of the hospital. Earlier a similar outbreak took the lives of 4 infants at Framingham Union Hospital, Framingham, June 2-15. An outbreak at Worcester City Hospital in October was responsible for the deaths of at least 10 babies before it ended in November. The State Department of Public Health is reported to be making an extensive investigation to determine the cause, Dr. Roy F. Feemster, director of the division of communicable diseases, said. The staff of Cambridge City Hospital was commended for efficiency in dealing with the crisis.

Appointments to the Teaching Staff at Harvard.—Recent appointments to the teaching staff at Harvard Medical School, Boston, include:

Dr. Robert E. Gross, Framingham, William E. Ladd professor of child surgery and head of the department of surgery at Children's Hospital.

Dr. William T. Green, Belmont, clinical professor of orthopedic surgery and director of orthopedic surgery at Children's Hospital.

Dr. Joseph S. Barr, Newton, clinical professor of orthopedic surgery and director of orthopedic surgery at Massachusetts General Hospital.

Dr. Charles A. Janeway, Weston, Thomas M. Rotch professor of pediatrics and head of the department of pediatrics at Children's Hospital.

Dr. Donald R. Wilson, Outremont, Quebec, research fellow in medicine.

Dr. Jacques A. Carlotti, Paris, France, research fellow in medicine.

Dr. Wade Volwiler, Athens, Ohio, assistant in medicine.

Dr. Louis A. Sieracki, Norwood, Mass., instructor in pediatrics.

Dr. Bertram Selverstone, Norfolk, Va., assistant in surgery.

Dr. Frederic C. Bartter, Boston, research fellow in medicine.

Dr. Thomas Lanier DeLorme, Randolph, Mass., research fellow in neurology.

Dr. Gardner Cowles Quarton, Cedar Rapids, Iowa, assistant in neurology.

Dr. Gustave Derouaux, Liége, Belgium, research fellow in physical chemistry.

Dr. Constance E. Field, London, research fellow in pediatrics.

Dr. Theodore Dunham Jr., Pasadena, Calif., Henry E. Warren fellow in surgery.

Martin Bernard Williamson, Ph.D., Las Vegas, N. M., instructor in ophthalmic research.

Dr. Sidney B. Luria, Waterbury, Conn., assistant in surgery.

Dr Ralph Henderson Kellogg, Saratoga Springs, N. Y., teaching fellow in physiology.

MICHIGAN

Grant for Research.—The United States Public Health Service has awarded Wayne University College of Medicine a grant of $10,000 in support of research on "The Pharmacology of Synoptic Function" to be carried on in the department of pharmacology and therapeutics under the direction of Dr. Amedeo S. Marrazzi, professor and head of the department.

Lecture by Charles Best.—Dr. Charles H. Best, Toronto, co-discoverer of insulin, was the speaker at a joint meeting of the Detroit Physiological Society and the Wayne University (Detroit) chapter of Sigma Xi, national honorary scientific society, February 4. Dr. Best discussed the agents which affect the metabolism of fat and their relation to the protection of the liver and the kidneys.

Secretaries and Public Relations Conference.—The Annual County Secretaries and Public Relations Conference of the Michigan State Medical Society was held February 2 in Detroit, with Dr. Gilbert B. Saltonstall, Charlevoix, acting as chairman. Dr. Creighton Barker, New Haven, secretary, Connecticut State Medical Society, opened the session with a discussion of public responsibilities of medical societies. The after dinner speaker was Governor Kim Sigler.

County Society Honors Veteran Members.—Houghton-Baraga-Keweenaw County Medical Society honored members of the society who have been practicing medicine forty years or more at a dinner recently. They are Drs. Addison D. Aldrich and Simon Levin, Houghton; James B. Quick, Laurium; William T. S. Gregg, Philip D. Bourland, Job R. W. Kirton, James C. Abrams and Andrew C. Roche, Calumet; George F. Brewington, Mohawk; Percy H. Wilson, Chassell; Melvin D. Roberts and Roy C. Whitmore, Hancock. Dr. Alfred LaBine, Detroit, presided.

Dr. McIntyre Goes to California.—Dr. Charles H. McIntyre, Kalamazoo, has accepted the position of chief of surgical service at the Veterans Administration hospital, Los Angeles, effective March 1. Dr. McIntyre, a graduate of the University of Michigan Medical School in 1931, was an instructor in the surgical department at University Hospital, Ann Arbor, before coming to Kalamazoo in 1936. He served in the navy in the Pacific areas during the recent war, attaining the rank of commander, and resumed his practice in Kalamazoo in January 1946. He is a specialist certified by the American Board of Surgery and was on the visiting staff of Borgess (Kalamazoo), Bronson Methodist (Kalamazoo), Sturgis Memorial (Sturgis) and Pennock (Hastings) hospitals.

MINNESOTA

Anniversary of Health Association.—Among the speakers at the recent celebration of the fortieth anniversary of the Minnesota Public Health Association were Drs. Lewis S. Jordan, Granite Falls, president, and William A. O'Brien, University of Minnesota Medical School, Minneapolis, director of postgraduate medical education and professor of preventive medicine and public health.

Sentenced for Crime of Abortion.—The Minnesota State Board of Medical Examiners reports that on Dec. 28, 1946, Clara O. Anderson, 48, 1142 Emerson Avenue North, Minneapolis, was sentenced to a term of three years at hard labor in the Woman's Reformatory at Shakopee by Hon. Levi M. Hall, judge of the district court of Hennepin County. The defendant had pleaded guilty to an information charging her with the crime of abortion and also with having had a conviction for similar offenses in 1943. On the same date Irene E. MacFarland, 46, 1514 Sixth Street North, Minneapolis, and Isadore Abramovich, 24, 706 Elwood Avenue North, Minneapolis, entered pleas of guilty to an information charging them with the crime of abortion in the same case with defendant Anderson. Judge Hall sentenced defendant MacFarland to one year in the Minneapolis Woman's Detention Home, suspended the sentence and placed the defendant on probation. Abramovich was sentenced to a one year term in the Minneapolis Work House, the sentence being suspended and the defendant placed on probation. None of the defendants are licensed to practice any form of healing in the state of Minnesota.

NEBRASKA

Tuberculosis Survey in Seventy-Three Locations.—From November 1945 to November 1946 a total of 41,263 4 by 5 free chest x-rays were taken in seventy-three different locations. Of these, 208 cases, or 5 per cent, showed persons to be sources for the spread of tuberculosis, and 470, or 1.1 per cent, were classified as suspected cases. There are 291 persons in hospitals or under the care of a private physician as a result of the survey. Fifty-seven counties have requested that the mobile unit of the state health department visit their communities.

Seminar on Poliomyelitis.—An intensive three day course of instruction for a selected number of physicians of the state was given January 9-11 by the National Foundation for Infantile Paralysis, the University of Nebraska College of Medicine and Creighton University College of Medicine. The course covered all phases of poliomyelitis, including early diagnosis, differential diagnosis, physical therapy, occupational therapy and the various aspects of convalescent care. One physician was selected by each of the councilors of the Nebraska State Medical Association with the expectation that each attending physician would return to his local medical group and report new developments.

NEW YORK

Richard Lyons Joins Syracuse University Staff.—The appointment of Dr. Richard H. Lyons as the Edward C. Reifenstein professor of medicine at Syracuse University College of Medicine, Syracuse, has been announced by Dr. H. G. Weiskotten, dean. Dr. Lyons, who is now associate professor of medicine at the University of Michigan School of Medicine, Ann Arbor, will assume his responsibilities at Syracuse this coming June. He is particularly well known for a series of papers on the development of a drug called "tetraethyl ammonium" helpful in vascular disease of the extremity, associated with poor blood flow.

Ward Helpers.—At a conference in December of leaders of District 1, New York State Nurses Association, of the Western New York Hospital Council and of professional nurse representatives of fourteen hospitals in the area, plans to introduce a ward helper program in western New York hospitals were completed. Harold A. Grimm, superintendent of Millard Fillmore Hospital, Buffalo, presided. Since there is no immediate hope of correcting the shortage of professional nurses in western New York institutions, ward helpers will be assigned to nursing departments in the hospitals to perform largely housekeeping duties, particularly in hospital wards, and to assist with some of the simpler procedures concerned with personal care of patients. They will be paid $90 a month during an apprenticeship and $100 when qualified for permanent employment. Interested women are urged to apply.

New York City

New Foundation for Research on Hypertension.—A gift of $1,000,000 to Beth Israel Hospital for a new foundation for medical research on hypertension has been established by Mr. and Mrs. Joseph Levy and will be known as the "Joseph and Helen Yeamans Levy Foundation, established in memory of their daughter Miriam Levy Finn." Dr. Arthur M. Fishberg, Beth Israel physician in chief and director of medical service, will serve the foundation as director. One objective of the foundation will be to furnish opportunities to young physicians and scientists.

Director of Laboratories Appointed.—Dr. Ward H. Cook, for seventeen years director of Bureau of Laboratories of the city of Yonkers, has been appointed to direct the laboratories at the Long Island College Hospital, Brooklyn, when the expansion program of the hospital, now under way, has been completed. Previously he taught pathology at Harvard Medical School, Boston, was assistant professor of bacteriology at the University of Pittsburgh and professor of pathology at the Medical College of Virginia, Richmond. He has also been pathologist to the New York Post-Graduate Medical School and Hospital, New York City.

Ten Cancer Detection Centers to Open at Once.—Fourteen new centers for the detection of cancer will be opened in the city. A grant of $187,835 is the first of a series to be provided by the New York City Cancer Committee, it was announced by General John R. Kilpatrick, chairman, board of managers, and Dr. John C. A. Gerster, chairman of the medical committee. The first ten centers will be opened at once, and negotiations are in progress for the remaining four. "These fourteen centers," said General Kilpatrick, "are the result of demands made on present cancer detection facilities. Their purpose is to provide a place for any one apparently well and without symptoms to go to make sure that he is free from the threat of cancer." The service will be provided at a moderate fee and if necessary the patient will be referred to his physician for treatment. Seven of the ten cancer centers are located in voluntary institutions which will receive appropriations totaling $57,995: Lennox Hill Hospital, Hospital for Joint Disease, New York University School of Medicine, Beekman-Downtown Hospital, Beth David and Staten Island hospitals and St. Vincent's Hospital in Staten Island. Three centers will be opened in connection with city hospitals and a welfare center, their appropriation totaling $21,640: Harlem Hospital, Welfare Island Dispensary and Kips Bay-Yorkville Health Center. The committee has also made three special grants for the extension of cancer facilities: Memorial Hospital $20,000 for additional personnel, Postgraduate Hospital $9,400 and Roosevelt Hospital $3,000. General Kilpatrick says the grants were the first of a series for medical service, education and research in the fight against cancer.

OHIO

Upholds Conviction on Abortion Charge.—The Ohio Supreme Court has upheld the conviction of Dr. Lloyd L. Jones, Columbus, in Franklin County Criminal Court on six counts of abortion. He must serve from six to forty-two years in Ohio Penitentiary. The Ohio court refused to review an appeal of his case from the district court of appeals, which had affirmed Dr. Jones's conviction in criminal court.

Industrial Hygiene Service.—New regulations for the prevention and control of industrial diseases went into effect January 1. They specify the maximum permissible amount on an eight hour exposure to sixty-two dusts, fumes, gases, mists and vapors to which workers can be exposed during employment. The regulations are being administered by the division of industrial hygiene, Ohio Department of Health. Since the work is primarily a service to industry and labor, it will function largely on a basis of requests from individual industries, labor organizations, health officers and physicians.

Society of General Physicians.—The general physicians of greater Cincinnati have formed a new organization called the Society of General Physicians, which is a federation of eleven member sections. The organization is dedicated to the advancement of the practice of general medicine and the realization of these purposes: 1. To define the functions of the practice of general medicine. 2. To promote the inclusion of general physicians in programs of postgraduate training. 3. To secure for general physicians in their hospitals the right to practice (in accordance with their ability and training) those arts and technics that lie within the scope of general medicine; the inclusion of general physicians as such, in their active medical staffs, and the right to vote and hold office in their medical staffs. Any physician who is an active member of the Academy of Medicine of Cincinnati, or who would be eligible for membership in the academy except for the fact that he does not reside in Hamilton County, Ohio, is eligible for membership in this society, the officers of which are Dr. Harry R. Mendelsohn, president, and Dr. F. William Vockell, 301 West McMillan Street, Cincinnati, secretary-treasurer.

PENNSYLVANIA

Special Course in Psychiatry.—A special three weeks' course in psychiatry is being conducted at the Warren State Hospital, Warren, by Dr. Milton H. Erickson, professor of psychiatry, Wayne University College of Medicine, Detroit, and Director of Psychiatric Research and Training, Eloise Hospital, Eloise, Mich. The course is being attended by members of other state institutions in Pennsylvania.

TEXAS

El Paso Medical Center.—A new medical center will be completed in El Paso early this year to meet the needs of the community, ten counties in west Texas, bordering counties in Arizona and New Mexico and the adjacent state of Chihuahua, Mexico. The $2,000,000 general hospital and adjacent nurses' residence and training school, to be known as Providence Memorial Hospital, will replace the existing Providence Memorial Hospital and will be held and operated in trust by a group of citizens who will serve as a board of trustees. The location of the medical center in El Paso was recommended by the U. S. Public Health Service and by the Texas Hospital Service. It will raise in the area the ratio of hospital beds from 2.08 per thousand to minimum standards of 4.5.

Dallas Southern Clinical Conference.—The annual spring conference of the Dallas Southern Clinical Society, March 17-20 in Dallas, will be held at the Adolphus and Baker hotels. The program has been planned to give the general practitioner and the specialist practical teaching. Guest speakers include Drs. Elmer Belt, Los Angeles, urology; William K. Boyd, Toronto, pathology; Franklin D. Dickson, Kansas City, orthopedic surgery; F. Bruce Fralick, Ann Arbor, Mich., ophthalmology; Leo H. Garland, San Francisco, radiology; George H. Humphreys, New York, surgery; John R. Lindsay, Chicago, otolaryngology; Perrin H. Long, Baltimore, preventive medicine; Henry G. Poncher, Chicago, pediatrics; Isadore S. Ravdin, Philadelphia, surgery; Ralph A. Reis, Chicago, obstetrics and gynecology; Newton D. Smith, Rochester, Minn., proctology; Williard O. Thompson, Chicago, medicine; John C. Whitehorn, Baltimore, neuropsychiatry, and Julius L. Wilson, New Orleans, medicine.

WASHINGTON

Hospital and University Affiliate.—The board of trustees of King County Hospital and the board of regents of the University of Washington have agreed to an affiliation between the school of medicine of the university and the King County hospital system. The staff of the hospital has been reorganized so that the early clinical teaching program of the medical school may be developed along both the undergraduate and the graduate program.

Spokane County Society Assisted Their Medical Veterans.—A plan was devised in Spokane in January 1942 to assist members of the Spokane County Medical Society who would enter the military service. Doctors who were commissioned as first lieutenants in the army, or the equivalent in other branches of the service, would have their income raised to that of a captain, thus providing them an extra $34, with an additional $10 for each dependent. All contributions to the Medical Officers' Beneficial Fund were voluntary; they continued throughout the war, and 87 per cent of the members contributed from $10 to $25 a month. A total of $66,027.50 was contributed by 134 members of the county society. As this amount exceeded the sum needed for the original purpose, it was decided to give also to each member who entered the service $150 for each period of six months he was away. These payments were made when the veterans were released from the service in order to help them resume civil practice. It was available, however, at any time during the war in case an emergency arose for the individual. Fifty doctors benefited from the fund, the smallest amount received by any one veteran having been $330 and the largest amount $2,334.16. Payments were made whether or not the veterans resumed practice in Spokane. Two wives of men who died in the service received payments from the time of the husband's entry until Sept. 1, 1946. Marjorie Weber, secretary to the Medical Officers' Beneficial Fund, writes that the final payments have just been made and that the books of the fund have been closed.

WEST VIRGINIA

Lifetime Memberships.—The council of the West Virginia State Medical Association has elected the following doctors to honorary lifetime membership: Drs. Oscar O. Eakle and Homer S. Brown, Sutton; Leonard W. Deeds, Buckhannon; G. M. Burton and Samuel H. Burton, Weston; James B. Dodrill, Webster Springs; Homer O. Van Tromp, French Creek; Charles B. Rohr, Alum Bridge, and S. H. Post, Clarksburg.

School Health Education. — A questionnaire entitled "Inventory of Secondary School Health Education Program in West Virginia" has been prepared and mailed to all principals of high schools in West Virginia. The committee submitting the inventory is composed of Miss Katherine Steinbicker, state consultant for the community health service project, department of education, Mrs. Grayce Hoke, Mr. A. J.

Gibson and Mr. L. K. Lovenstein. The replies to the questionnaire will be used in setting up comprehensive objectives and in implementing a health education program to meet the needs and interest of high school students in the state.

Cancer Information Centers.—West Virginia's first cancer information center has been opened at 207 Bradford Street in Charleston. It is being financed from funds collected in the annual cancer drive of the American Cancer Society. The center is open to the public each weekday from 9 until 5. Literature is being distributed, and information is available to persons interested in cancer control. Applications of needy cancer patients for financial aid through the division of cancer control are handled by Mrs. Frances Meyer, who is in charge of the center and who attends the two tumor clinics in Charleston. Plans are being completed for the opening of an information center at 77 Twelfth Street, Wheeling, with Miss Virginia Ewing, a graduate in social service from Wooster University, in charge. A third center will be opened in Clarksburg early in the spring.

GENERAL

Eye Bank Grants Fellowship.—The Eye Bank for Sight Restoration, Inc., has announced that the first international fellowship to be granted by the eye bank is to be awarded to an ophthalmologist of the Hebrew University in Palestine in ophthalmology and research work under the direction and supervision of the Wilmer Institute of Johns Hopkins University, Baltimore.

Infantile Paralysis Research Meeting.—Scientists and physicians engaged in infantile paralysis research recently conferred in Chicago on setting up standard practices and methods for use of curare in relieving muscle spasms at the acute stage of poliomyelitis. Harry M. Weaver, Ph.D., director of research, National Foundation for Infantile Paralysis, which sponsored the meeting, presided.

Norton Award to Dr. Bernheim.—The $3,500 Norton Medical Award for 1947 has been made to Dr. Bertram M. Bernheim, Baltimore, for his book "A Surgeon's Domain." The award is made for the best book by a professional man written for the layman. Dr. Bernheim is associate professor of surgery at the Johns Hopkins Medical School, Baltimore, and visiting surgeon to the Johns Hopkins Hospital.

Warning of Impostor.—Brooks Mendell, New York, is visiting various research and treatment centers in the United States representing himself as an authorized agent of the National Foundation for Infantile Paralysis. Dr. Hart E. Van Riper, medical director of the foundation, advises that Mendell has no connection with the National Foundation for Infantile Paralysis, nor has he been authorized to contact any institution or laboratory where work is in progress under a grant from the foundation.

Pan American Congress of Ophthalmology.—The third Pan American Congress of Ophthalmology will be held in Havana, Cuba, Feb. 23-28, 1948. Papers should be in the hands of the committee by February 23 for official subjects. No program changes can be made after August 23. Papers should be accompanied by an official summary of 300 to 500 words for the official subjects and from 200 to 300 words in the free communications. Those who wish to attend the congress should send their names to Dr. Tomas R. Yanes, P. O. Box 970, Havana, Cuba.

Research Fellowship Awarded.—The first of the American College of Physicians Research fellowships for 1947-1948 has been awarded Dr. Thomas F. Paine Jr., Cambridge, Mass., who will continue studies of infectious diseases with special reference to chemotherapy and the use of antibiotics at the Thorndike Memorial Laboratory, Boston City Hospital. Dr. Paine is a graduate of Vanderbilt University School of Medicine, Nashville, 1942, interned at Strong Memorial Hospital, Rochester, N. Y., and during his service in the Army of the United States participated in clinical and laboratory studies of infectious diseases.

Unprecedented Turnover in Deanships.—The *Diplomate* for December 1946 reports that since the 1945 annual meeting of the Association of American Medical Colleges an unprecedented turnover has occurred in deanships, three resulting from deaths and twenty due to resignation or retirement. Nineteen new deans have been appointed. Three schools are without a dean and are seeking men to fill the vacancies. One dean will retire as soon as a successor is found. When these positions are filled there will have been twenty-three new deans since October 1945. Since there are only seventy-eight medical schools in the United States and ten in Canada, this is a 25 per cent turnover.

Applications for Aid for Research in Sex Problems.—Applications to the National Research Council Committee for Research in Problems of Sex for financial aid during the fiscal year beginning July 1, for work on fundamental problems of sex and reproduction, should be received not later than April 1. They may be addressed to the chairman, Robert M. Yerkes, Ph.D., Yale School of Medicine, New Haven 11, Conn. Although hormonal investigations continue to command the interest and support of the committee, preference, in accordance with current policy, will ordinarily be given to proposals for the investigation of neurologic, psychobiologic and behavioral problems of sex and reproduction.

Aid for Superior Students.—The Walter Joseph Meek Fund has recently been established for students of the University of Wisconsin Medical School, Madison, by Dr. Anton J. Carlson, Frank P. Hixan distinguished service professor emeritus of physiology at the University of Chicago, a former pupil, in recognition of Dr. Meek's superior performance in teaching research and public service. The fund is intended for superior and financially needy students in the medical sciences. Dr. Carlson contributed $400. Dr. Paul Hodges, professor of roentgenology at the University of Chicago, contributed an additional $100. It is expected that this fund will increase with donations from former students and colleagues of Dr. Meek.

Training Conferences on Poliomyelitis.—Area staff training conferences on the subject of poliomyelitis are being sponsored by the American Red Cross. The Midwestern Area conference met January 23-24 in St. Louis, the Pacific Area in San Francisco January 27-28, and the Southeastern Area at Atlanta, Ga., February 10-11. Other conferences planned are for the Eastern Area at Alexandria, Va., February 26-27; North Atlantic Area at New York City, April 2-3. The purpose of each meeting is to prepare staff nurses to judge nursing needs in poliomyelitis outbreaks, to bring them up to date on procedures and available facilities and to discuss problems encountered in nurse recruitment and assignment. Representatives of the National Foundation for Infantile Paralysis and the Children's Bureau will be present at each meeting.

Lost or Stolen Narcotic Order Forms.—The Office of the Commissioner of Narcotics, Washington 25, D. C., has again announced the numbers of those order forms for opium and other narcotics which have been reported and are probably in the hands of persons not entitled to them. These numbers are in addition to the order forms reported lost in narcotic circular *283, July 9, 1946. Wholesale dealers in narcotics,* importers and manufacturers are warned not to fill any order form on which any of the numbers reported appear or any form listed in circular *283* (except numbers A312167-170, R132381-390 and R568761-770, all inclusive, which have been found). Any order form presented on which the serial number is listed in these two circulars should be forwarded to the Office of the Commissioner of Narcotics at once.

Deaths in Other Countries

Sir Edward Thornton, formerly secretary for public health and chief health officer for the Union of South Africa and D. G. M. S. of the Union Defense Forces with rank of brigadier, died Oct. 26, 1946, aged 68.——**Dr. Gonzálo Castañeda,** dean of the National Academy of Medicine, Mexico City, died recently, aged 78.——**Dr. Charles Fenwick Wilde,** former physician at Montreal General Hospital, Montreal, Que., and administrator in medicine at McGill University, died Nov. 24, 1946, aged 80.——**Sir William J. Collins,** former vice chancellor of London University, consulting surgeon at Royal Eye Hospital, died Dec. 12, 1946 in London.

Marriages

William Somers Reynolds Jr., Wetumpka, Ala., to Miss Jean Vaughan Ferebee of Norfolk, Va., in October.

Stanley Willard Wright, Berkeley, Calif., to Dr. Phyllis Richman Mann of New York November 16.

Victor Hill Klein Jr., Knoxville, Tenn., to Miss Frances Lathan Perkins at Memphis recently.

DeArmond Moore, Charlotte, N. C., to Miss Leona Rose Olander of Pittsburgh October 8.

Otto A. Miller, Ashland, Pa., to Miss Pearl Zimmerman of Buck Run in September.

Wesley M. Page, Bedford, Iowa, to Miss Betty Jane Thomas of Iowa City September 27.

Deaths

John Favill ⊕ Chicago; born in Madison, Wis., on Sept. 9, 1886; Harvard Medical School, Boston, 1913; professor of neurology at the University of Illinois College of Medicine; interned at the Massachusetts General Hospital in Boston; specialist certified by the American Board of Psychiatry and Neurology; for many years on the faculty of Rush Medical College; fellow of the American College of Physicians, American Psychiatric Association, American Association for the Advancement of Science and the Institute of Medicine of Chicago; member of the Society of Medical History of Chicago, Chicago Society of Internal Medicine, Chicago Academy of Criminology, American Neurological Association, serving at one time as its vice president, Illinois Psychiatric Society, Association for Research in Nervous and Mental Diseases, Association for the Study of Internal Secretions, Illinois Society for Mental Hygiene, National Committee on Maternal Health, Illinois Birth Control League, National Medical Committee on Federal and State Contraceptive Legislation, National Medical Council on Birth Control, National Committee on Planned Parenthood, Birth Control Federation of America and many others; member and past president of the Chicago Society for Personality Study, Chicago Neurological Society and Central Neuropsychiatric Association; served with the American Expeditionary Forces in France during World War I; colonel, medical reserve corps, not on active duty; served in various capacities on the staffs of the Central Free Dispensary, Illinois Institute for Juvenile Research, Institute for Psychoanalysis, St. Luke's, Cook County, St. Elizabeth, Highland Park (Ill.), and the Presbyterian hospitals; author of "Outline of the Cranial Nerves," "Primer of Celestial Navigation" and others; trustee of the Rogers Memorial Sanitarium in Oconomowoc, Wis., and Elizabeth McCormick Memorial Fund; died at his home in Winnetka, Ill., Dec. 21, 1946, aged 60, of coronary thrombosis.

George Andrew Chapman ⊕ Glen Falls, N. Y.; Baltimore Medical College, 1897; past president of the Medical Society of the State of New York and the Warren County Medical Society; veteran of the Spanish-American War; member of the American Public Health Association, American Association for the Advancement of Science, American Congress of Internal Medicine, New York State Society of Internal Medicine and the Sanitary Officer Association of State of New York; fellow of the American College of Physicians; for many years health officer of Queensbury; affiliated with the Glen Falls Hospital; died Dec. 16, 1946, aged 75, of uremia.

Ernest Dwight Chipman ⊕ San Francisco; Yale University School of Medicine, New Haven, 1897; an Affiliate Fellow of the American Medical Association; specialist certified by the American Board of Dermatology; member and formerly vice president of the American Dermatological Association; member of the House of Delegates of the American Medical Association in 1915 and 1916 and chairman, Section on Dermatology and Syphilology, 1921-1922; served on the staffs of the Mary's Help Hospital, French Hospital and the Franklin Hospital; died Dec. 4, 1946, aged 71, of Parkinson's disease.

Robert Louis Lee, Kansas City, Kan.; University of Kansas School of Medicine, Kansas City, 1929; member of the American Medical Association; interned at the New Charleston General Hospital and Training School in Charleston, W. Va.; began active duty as a captain in the medical reserve corps of the U. S. Army in March 1941; promoted to major; served overseas; released from active duty on June 20, 1945; secretary of the Bethany Hospital staff; surgeon for the Atchison, Topeka and Santa Fe Railroad; died Nov. 28, 1946, aged 43, of coronary occlusion.

A. Bennett Cooke, Los Angeles; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; clinical professor of surgery at the College of Medical Evangelists; formerly on the faculty of his alma mater; member of the American Medical Association, serving as a member of its House of Delegates in 1911, 1912 and 1913 and Judicial Council from 1911 to 1918; fellow of the American College of Surgeons; on the staffs of the Los Angeles County Hospital, Presbyterian Hospital-Olmsted Memorial, California and Methodist hospitals; died Dec. 9, 1946, aged 79.

Leon James Barber ⊕ Patchogue, N. Y.; University of Vermont College of Medicine, Burlington, 1913; served during World War I; on the staff of the John T. Mather Memorial Hospital in Port Jefferson; died Dec. 23, 1946, aged 58.

George Evans Beatty, Brooklyn; Long Island College Hospital, Brooklyn, 1912; served on the staffs of the Norwegian, Caledonian and Prospect Heights hospitals; died Dec. 16, 1946, aged 58, of heart disease.

Eli Thomas Brand, Wilmette, Ill.; Washington University School of Medicine, St. Louis, 1908; died Dec. 23, 1946, aged 63, of chronic myocarditis.

Frank T. Brigham, Watkins, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; member of the American Medical Association; died in Rochester recently, aged 66, of bronchopneumonia and carcinoma of the prostate.

Hugh Ria Brownlee, Cleveland; University of Buffalo School of Medicine, 1900; on the staff of the Huron Road Hospital in East Cleveland, where he died Dec. 5, 1946, aged 76, of coronary thrombosis.

Sherman Moran Burns ⊕ Oswego, N. Y.; Syracuse University College of Medicine, 1920; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; president of the Fifth District Branch of the Medical Society of the State of New York; on the staff of the City Hospital; died Dec. 15, 1946, aged 54, of coronary thrombosis.

Foster Kendrick Camp, Pasadena, Calif.; Dearborn Medical College, Chicago, 1906; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died Dec. 4, 1946, aged 72, of intestinal obstruction.

Ernest Marion Carson, Rembert, S. C.; Medical College of the State of South Carolina, Charleston, 1905; died Dec. 2, 1946, aged 67.

Archie Leonard Clayton, Fort Payne, Ala.; Chattanooga (Tenn.) Medical College, 1905; found dead Dec. 8, 1946, aged 74.

Henry L. Cody, St. Louis; St. Louis College of Physicians and Surgeons, 1898; also a graduate in pharmacy; died January 14, aged 73, of angina pectoris.

Waller Glenmore Combs, Kirksville, Ky.; University of Louisville Medical Department, 1906; served during World War I; died Dec. 8, 1946, aged 63, of heart disease.

Robert Houk Cox, Murphy, N. C.; University of Tennessee College of Medicine, Memphis, 1940; interned at St. Joseph's Hospital in Memphis; member of the American Medical Association; member of the staff of the Petrie Hospital; died Dec. 7, 1946, aged 33, of skull fracture received when he fell from a ladder while trying to escape from a fire in the Winecoff Hotel in Atlanta, Ga.

Homer Winfield Crane ⊕ Berkeley, Calif.; Cooper Medical College, San Francisco, 1909; major, medical reserve corps, not on active duty; member of the staff of the Alta Bates Hospital; died Dec. 19, 1946, aged 65.

George L. Cremeens, Springerton, Ill.; Keokuk (Iowa) Medical College, 1895; member of the American Medical Association; served as village president; died Dec. 22, 1946, aged 78.

Joseph M. Croman Sr. ⊕ Mount Clemens, Mich.; Detroit College of Medicine, 1892; served as police commissioner and as county physician; on the staff of St. Joseph Sanitarium and Hospital, where he died Dec. 10, 1946, aged 81, of coronary thrombosis.

Deborah Vivian Rubenstein Dauber ⊕ Chicago; Boston University School of Medicine, 1938; diplomate of the National Board of Medical Examiners; interned at the Mount Sinai Hospital in Cleveland; interned and served a residency at the Michael Reese Hospital, where she was a member of the cardiovascular research division and where she died Nov. 21, 1946, aged 32, of injuries received when struck by an automobile.

Domnick Patrick Dempsey ⊕ Kellogg, Minn.; John A. Creighton Medical College, Omaha, 1906; member of the American Medical Association; died in St. Mary's Hospital, Rochester, Nov. 30, 1946, aged 76, of fracture of the left hip received in a fall and arteriosclerosis.

Thomas Claude Donald ⊕ Birmingham, Ala.; Medical College of Alabama, Mobile, 1897; president of the board of education of the city schools of Bessemer, Ala., from 1920 to 1925; member of the Southern Medical Association; on the staff of Baptist Hospital; died Dec. 5, 1946, aged 70, of cardiovascular disease.

Henry Beaman Douglass, East Boothbay, Maine; College of Physicians and Surgeons, medical department of Columbia College, New York, 1886; member of the American Medical Association, Medical Society of the State of New York and the American Laryngological, Rhinological and Otological

Society; at one time professor of diseases of the nose and throat at the New York Post-Graduate Medical School and Hospital, Columbia University, New York; died in West Palm Beach, Fla., Dec. 5, 1946, aged 80, of coronary thrombosis.

Kirby Dwight ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1905; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; served as president of the Medical Society of the County of New York, as trustee and member of many committees of the New York Academy of Medicine and as treasurer of the Medical Society of the State of New York; on the staffs of the Lincoln and Roosevelt hospitals; died Dec. 3, 1946, aged 67.

John Joseph Ederer, Minneapolis; University of Minnesota Medical School, Minneapolis, 1930; member of the American Medical Association; interned at the U. S. Marine Hospital, Stapleton, Staten Island, N. Y.; formerly medical superintendent and owner of the Mahnomen (Minn.) Hospital; for three years examining physician for the Selective Service in Mahnomen County; died Dec. 11, 1946, aged 41, of coronary thrombosis and pneumonia.

George Boardman Edwards, Darlington, S. C.; Medical College of the State of South Carolina, Charleston, 1901; member of the American Medical Association; honorary member of the South Carolina Medical Association; served as mayor and as county coroner; died in the McLeod Infirmary, Florence, Dec. 13, 1946, aged 72, of carcinoma.

Elmer Sylvester Erhard ⊕ Curwensville, Pa.; Medical Department Western University of Pennsylvania, Pittsburgh, 1906; president of the school board; served as county coroner and a term as burgess; for many years medical examiner for the local draft board; on the visiting staff of the Clearfield (Pa.) Hospital; died Dec. 2, 1946, aged 69, of coronary thrombosis.

Emerson Armor Fletcher, Milwaukee; University of Pennsylvania Department of Medicine, Philadelphia, 1892; member of the American Urological Association; fellow of the American College of Surgeons; served on the staffs of the Milwaukee, St. Mary's and Milwaukee Children's hospitals; died Dec. 6, 1946, aged 77, of arteriosclerosis.

Julius Henry Philip Gauss ⊕ Indianapolis; Rush Medical College, Chicago, 1903; assistant professor of medicine at the Indiana University School of Medicine; interned at the Michael Reese Hospital in Chicago, where he was on the staff of the Alexian Brothers' Hospital from 1908 to 1912; at one time fellow in medicine at the Mayo Foundation, Rochester, Minn.; formerly on the faculty of his alma mater; on the staffs of the Methodist and St. Vincent's hospitals; died Oct. 31, 1946, aged 74, of cerebral thrombosis.

Matthew Gerard Golden, Brooklyn; Fordham University School of Medicine, New York, 1919; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Oto-Laryngology; served as assistant clinical professor of otolaryngology at the Long Island College of Medicine; on the staffs of the Kings County Hospital, St. Peter's Hospital, Victory Memorial Hospital and the Midwood Hospital; died Nov. 11, 1946, aged 52.

Philip Hartson Greeley ⊕ Concord, N. H.; Dartmouth Medical School, Hanover, N. H., 1897; member of the Maine Medical Association; died Dec. 2, 1946, aged 76, of arteriosclerosis.

Edgar James Haines, Medford, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; member of the American Medical Association; served on the staff of the Burlington County Hospital in Mount Holly; died Nov. 5, 1946, aged 67, of cardiovascular disease.

John Allan Ilderton, Yemassee, S. C.; Medical College of the State of South Carolina, Charleston, 1911; died Nov. 4, 1946, aged 60.

William Eli McCormack ⊕ Major, U. S. Army, retired, Sarasota, Fla.; University of Louisville Medical Department, 1911; Army Medical School and Medical Field Service School in 1921; at one time professor of microscopic anatomy at the University of Louisville Medical Department; entered the medical corps of the U. S. Army in 1918; served during World War I; retired on Dec. 31, 1932 for disability in line of duty; died in the Moore County Hospital, Pinehurst, N. C., Sept. 5, 1946, aged 59, of coronary occlusion.

George Coe Merriman, Lake Como, Pa.; Albany (N. Y.) Medical College, 1897; member of the American Medical Association; veteran of the Spanish-American War; died Nov. 16, 1946, aged 71.

Heber Guy Morgan, Red Lodge, Mont.; College of Physicians and Surgeons, Baltimore, 1906; member of the American Medical Association; died Nov. 26, 1946, aged 63, of carcinoma of the liver.

John Matthew Mras, Trenton, N. J.; Medico-Chirurgical College of Philadelphia, 1916; at one time superintendent of the Chester County Hospital for the Insane in Embreeville; died in St. Francis Hospital Nov. 12, 1946, aged 54, of ruptured esophageal varix and diabetes mellitus.

George James Musgrave ⊕ Chicago; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; assistant clinical professor of otorhinolaryngology at the Loyola University School of Medicine; fellow of the American College of Surgeons; on the staffs of the Provident and Mercy hospitals; died in Henrotin Hospital Nov. 28, 1946, aged 70.

John Rudolph Nenninger, Westfir, Ore.; University of Cincinnati College of Medicine, 1940; member of the American Medical Association and Ohio State Medical Association; interned at the Christ Hospital in Cincinnati; served in the medical corps, U. S. Naval Reserve, during World War II and was released in March 1946 from active duty with rank of lieutenant commander; died in Eugene Nov. 3, 1946, aged 39, of acute leukemia.

John Howard Norris, Fostoria, Ohio; University of Wooster Medical Department, Cleveland, 1877; Bellevue Hospital Medical College, New York, 1880; served on the staff of the City Hospital, where he died Nov. 25, 1946, aged 90, of acute suppurative appendicitis and peritonitis.

Harry Theron Pitman, Chulumani, Bolivia, South America; College of Medical Evangelists, Loma Linda-Los Angeles, 1940; served an internship and residency at the General Hospital of Fresno County in Fresno, Calif.; commissioned a first lieutenant in the medical reserve corps of the U. S. Army and was later honorably discharged; in charge of the Chulumani Sanitarium and Hospital; killed in an airplane accident Nov. 8, 1946, aged 34.

Walter Robert Rieck ⊕ Kearny, N. J.; Long Island College Hospital, Brooklyn, 1906; died in West Hudson Hospital, Kearny, Nov. 4, 1946, aged 64, of cirrhosis of the liver and gastric hemorrhage.

John Henry Rinehart, Moran, Kan.; Eclectic Medical University, Kansas City, 1903; served during World War I; died Nov. 2, 1946, aged 73, of cerebral hemorrhage.

Eugene C. Roseberry, Springfield, Mo.; Rush Medical College, Chicago, 1895; member of the American Medical Association; member of the medical board of the Missouri State Sanatorium, Mount Vernon; on the associate staff of the Burge and St. John's hospitals; on the staff of the Springfield Baptist Hospital, where he died Nov. 29, 1946, aged 78, of coronary thrombosis.

Chester I. Sater, Albion, Idaho; Barnes Medical College, St. Louis, 1909; member of the American Medical Association; died in the Rupert (Idaho) General Hospital Nov. 15, 1946, aged 62, of heart disease.

Harold Clinkscales Shirley, Charlotte, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1918; member of the American Medical Association; on the staff of the Memorial Hospital; died Nov. 28, 1946, aged 55, of cerebral hemorrhage.

Carl Miller Sneed ⊕ Columbia, Mo.; University of Missouri School of Medicine, Columbia, 1901; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; served during World War I; on the staff of the Boone County General Hospital; died Nov. 6, 1946, aged 69, of coronary thrombosis.

Joseph John Sweeney, Philadelphia; Temple University School of Medicine, Philadelphia, 1927; school doctor in Yeadon, Pa.; interned at St. Mary's Hospital; served a residency at the Doctors Hospital, where he later became a member of the staff and where he died Nov. 27, 1946, aged 47, of uremia.

Dale Edward Thomas ⊕ Saginaw, Mich.; University of Michigan Medical School, Ann Arbor, 1928; past president of the Saginaw County Medical Society; on the visiting staffs of St. Mary's and St. Luke's hospitals; on the staff of the Saginaw General Hospital; died Nov. 5, 1946, aged 42, of cerebral hemorrhage.

Charles Edward Westerhout, Brea, Calif.; College of Medical Evangelists, Loma Linda-Los Angeles, 1929; interned at the Portland Sanitarium and Hospital in Portland, Ore.; served during World War II; on the staff of the Fullerton (Calif.) Hospital; died in the Veterans Hospital, Oakland, Nov. 20, 1946, aged 44, of myelogenous leukemia.

Socialistic Medical Bodies and the Health Service

A meeting of the representative body of the British Medical Association will be held on January 28 to decide whether the association will negotiate with the minister of health or not as to the terms under which the profession will work the national health service. As reported in a previous letter, the council of the association has advised the representatives to decline to negotiate and it seems probable that they will do so. This has led to a move by a body which is antagonistic to the British Medical Association, the Medical Practitioners Union. It has a membership of 4,000 against the 58,000 of the British Medical Association and is a registered trade union. It claims to be nonpolitical, but the dermatologist Sir Ernest Graham-Little, who is the most prominent figure among medical members of Parliament, refers to it as a socialistic body. He evidently regards trade unionism as socialistic. In theory there is a clear difference between socialism and trade unionism. A trade union is simply a combination of the workmen in a particular trade to promote their interests by collective negotiation, restrictive practices and strikes, often to detriment of the community. Socialists, on the other hand, want the state to take over and carry on industries now in the hands of private enterprise. But in present British politics the distinction has disappeared, for the government, which has begun to socialize the great British industries, derives most of its support from the trade unions. The Medical Practitioners Union has sent a circular to doctors stating that the representative body of the British Medical Association at its coming meeting on January 28 will probably decide not to negotiate with the minister of health. Doctors who intend to enter the new service are told that in their own interests they should be represented at the negotiations. It is claimed that the union has studied for many years the question of a state service, and is therefore in a favorable position for such negotiation.

There is another body, the Socialist Medical Association, with a membership of 3,000. There is no question as to the applicability of the term "socialist" here, but there is as to the term "medical," as the majority of the members are not drawn from the medical profession. Those who are amount to less than 1 per cent of the profession. It is obvious that in the coming struggle with the government over the new act these bodies, whether truly socialistic or of socialistic affinity, are likely to cause trouble. The British Medical Association has tried as far as possible to keep politics out of the struggle, but it is of little use to appeal to doctors of socialistic convictions to do this.

Treatment of Traumatic Paraplegia

At the Section of Neurology of the Royal Society of Medicine, Dr. L. Guttmann described the prognosis and treatment of traumatic paraplegia on the basis of 177 cases treated at a center for spinal injuries. The patients were received at different intervals after injury, some with sepsis and contractures. On admission they were often undernourished. Food was considered important in treatment, a high protein intake being essential to replace that lost through pressure sores or urinary infection. The most important measure in the prevention of sores was continual change of posture by day and by night. Infection was controlled by chemotherapeutic agents, and necrotic portions were excised. Dressings should be changed once or twice a day.

In the management of the bladder, neither urethral catheterization nor suprapubic cystotomy had proved wholly satisfactory. Every patient admitted with a cystotomy always had infected urine, often with severe ascending infection. There are indications for cystotomy, such as urethral stricture, but there is no case for its adoption as a routine. When adopted it should be discontinued as soon as possible and replaced by washouts through a catheter or indwelling catheter to reduce infection. Distention of a painless bladder below the level of the lesion sets up a widespread reflex, with flushing of the head and neck, nasal occlusion, raised blood pressure, slow pulse and respiratory discomfort. This reflex proved a valuable guide to distention and reduced the call for acetylsalicylic acid to relieve headache.

Mental changes may be due to infection. An early sign is querulous or rude behavior. Reactive mental disturbance also occurs from psychologic shock. It is essential to secure the patient's cooperation and to surround him with an optimistic atmosphere. The aim should be to reduce the period of recumbency and restore independence as soon as possible. Contractures and atrophy must be guarded against by keeping paralyzed limbs in proper position. The worst contractures are seen in patients who have been in plaster beds. Passive movements are begun at once. Intramedullary injection of 1 cc. of 90 per cent alcohol controls flexor spasm for three or four weeks.

A New Journal Devoted to Nutrition

The Central Council for Health Education announces the publication of a new bimonthly, the *Nutrition Bulletin*, in January. Its object is to deal not with the basic principles of nutrition but with their application to social betterment. Thus it will deal with the growth of the various nutrition services, public instruction, food habits, and the place of diet in the national health. The purpose is to inform all concerned in improving the nation's diet. The address is Tavistock House, Tavistock Square, London, W. C. 1. The annual subscription is 3 shillings.

ITALY

Surgical Association of Piedmont

Two preliminary sessions of the National Convention of Medicine and Surgery have been held recently by the Surgical Association of Piedmont in cooperation with the Academy of Medicine of Turin. These meetings were devoted exclusively to results of treatment of tumors of the colon. Among the speakers were Professors S. Battistini, E. Zilocchi, Mottura, Bertocchi and Colombo.

Professor Zilocchi reviewed the histories of 115 patients with tumors of the colon who recovered at the surgical clinic of the University of Turin. He confined his remarks to the surgical treatment of 62 patients who recovered during the period 1936 to 1945. Only 28 of these had radical operations performed. The death rate in this group was 41.9 per cent and the death rate in those treated by palliative means when occlusion was present and the radical operation was not carried out was 44 per cent. Professor Mottura reported the results of 88 necropsies which had been performed at the anatomicopathologic institute of the University of Turin. Natural death had occurred in 48 of the patients and peritonitis was observed in about 50 per cent. Incidence of bronchopneumonia was high. Professor Bertocchi discussed the circulation of the colon and stated that this was poor in three regions: the terminal segment of the ileum, the transverse colon and the sigmoid. This suggests that in right hemicolectomy dissection of the small intestine may be performed 20 to 30 cm. distant from the ileocecal valve after ligation of the ileocolic artery.

PALESTINE

(From Our Regular Correspondent)

JERUSALEM, Jan. 1, 1947.

Method of Prolonging the Action of Local Anesthetics

The prolongation of the action of drugs on the organism has been attempted repeatedly, lately in the case of the antibiotics. Rappoport (*Acta med. orient.* **5**, April 1946) has published a new method which he demonstrates with benzocaine. The drug is dissolved in a nonwatery medium (urethane-methylacetamide); when this solution comes in contact with water, benzocaine is rapidly precipitated.

On injection of this benzocaine solution into body tissues the contact with the body fluids provokes a precipitation of the benzocaine. The solvent is quickly absorbed, and benzocaine remains at the site of the injection in the form of a nonwater soluble, finely distributed substance. The anesthetic action continues until the benzocaine is completely absorbed. A depot of benzocaine is thus formed. In animal experiments with rabbits an anesthesia of two to four weeks' duration could be observed. No tissue damage was seen microscopically at the site of the injection.

In the same number Spira reports clinical experiments with this new principle in 47 cases in which 290 injections had been made. The injections were given endoneurally, perineurally, intra-articularly and by infiltration. The amount of the 2 per cent solution used was between 0.2 and 5 cc. The effect of the anesthetic lasted up to fourteen months. Cases of pruritus ani, epicondylitis, muscular spasm, causalgia, ischialgia, neuroma and humeroscapular contraction were treated. As the injections are very painful, the site of the injection was previously anesthetized by infiltration or nerve block with a 1 per cent watery procaine solution.

Spira points out that, if possible, the injection should not be given into inflamed tissue. The infiltration or the nerve block with procaine is executed with the usual technic; the needle is not removed, but 0.2 to 5 cc. of the benzocaine solution is injected at the same site as soon as anesthesia has set in. Subcutaneous injection is to be avoided.

Virus Myocarditis

Lyon discusses the problem of acute myocarditis as a sequel to infectious mononucleosis in the *Acta med. orient.* **5**:228, 1946. His observations represent an interesting contribution to the problem of virus myocarditis; he presents a case of infectious mononucleosis in which, in the course of four months, considerable changes were found in the electrocardiogram. These changes, which disappeared again completely, consisted mainly of a characteristic negative T deflection in CF_2. The clinical diagnosis was ascertained by a positive Paul-Bunnell test, a specific blood count and typical glandular involvement. Virus myocarditis is of special interest because in Palestine a very slow convalescence is characteristic in the numerous cases of infectious hepatitis and infectious mononucleosis.

Histochemical Method for Staining Kerasin

At a monthly scientific meeting held in the Institute of Pathological Anatomy and Histology of the Hadassah Hospital and Hebrew University, Jerusalem, Professor S. Franco and Dr. M. Wolman demonstrated a new histochemical method for staining kerasin in tissues of patients suffering from Gaucher's disease. The method consists in immersion of frozen sections for thirty minutes in boiling distilled water, buffered at p_H 4, followed by the usual treatment with sudan III. The method can be made specific for cerebrosides by extracting the sections with ether and acetone before staining. The authors believe that the immersion of the sections in boiling water separates the kerasin from a lipoproteic complex.

Hepatic Complications of Amebiasis

In the *Journal of the Palestinian Arab Medical Association* of September 1946 Canaan reports the occurrence of liver complications in amebiasis. He finds that 27.5 per cent of the Palestinian Arabs are infected with Endameba histolytica. Amebic dysentery represents one third of all cases of dysentery in Palestine.

Hepatic complications in Arabs are found statistically to occur in 0.27 per cent of hospital cases. The total number of patients under review was 41,550: at the French Hospital, Bethlehem, from 1935 to 1944, 10,500; at the German Hospital, Jerusalem, in five years, 9,690, and at the French Hospital, Jerusalem, from May 1934 to April 1946, 21,360.

SPAIN

(From Our Regular Correspondent)

MADRID, Dec. 17, 1946.

Alloxan Diabetes

In the medical life of Spain recently one of the studies which will no doubt have wide repercussions was done by Dr. Grande Covian, late assistant professor of physiology in the Medical School of Madrid University, who is now working in the Institute for Medical Research under the direction of Professor C. Jimenez Diaz and concentrating on the problem of alloxan diabetes.

His experiments on dogs began in the spring of 1944. In the first comparative experiment with diabetes caused by removal of the pancreas and diabetes produced by high doses of alloxan, he observed that the latter form was more serious, which led him to visualize the existence of extrapancreatic factors in its production. He then produced cases of slight diabetes, which were spontaneously curable by small doses of alloxan, it being observed that a second injection of alloxan in diabetogenous doses was absolutely inefficacious in these animals. This observation led the investigators to describe such cases as "resistant to alloxan" (or "alloxan resisting"). So far, these cases seem to have been ignored by other investigators.

On studying the causative mechanism of this state of resistance, Dr. Grande observed a rapid destruction of the alloxan in contact with the blood and tissues, this concurring with the result obtained when an attempt was made to determine chemically the degree of alloxan in the blood; with this observation is has become possible to calculate the amount of time needed for the destruction of alloxan, avoiding contact between it and certain viscera.

Furthermore, he saw that if the alloxan did not circulate through the pancreas owing to a ligature in the vessels of that organ, the animal to which diabetogenous doses were injected died with all the symptoms of uremia. To avoid uremia they made the alloxan injection in animals with their renal pedicles temporarily tied; not only did these animals not develop uremia, but they were not diabetic either. If a further dose of alloxan was injected later, they then contracted diabetes. The circulation of alloxan through the kidney therefore seems to be necessary for the development of diabetes and the establishment of resistance to alloxan.

The direct injection of alloxan into the pancreas does not produce diabetes, although disturbances are observed in the β cells of the islets. Therefore, alloxanic diabetes does not appear to be a purely pancreatic form of the disease.

The successive communications on this great work of Dr. Grande Covian's and his associates, Dr. Oya especially, have appeared in the *Revista Clinica Española;* it is to be expected that the investigators will go on producing interesting results.

Correspondence

APPARENT SENSITIVITY TO AMIGEN

To the Editor:—The clinical note entitled "Apparent Sensitivity to Amigen," by Drs. Harris, Gordon, Gray and Barton (THE JOURNAL, Nov. 30, 1946, p. 785) described the attempted suicide of a girl aged 17, who took 125 grains (8.1 Gm.) of phenobarbital. She rapidly went into coma and by the fourth day a fatal outcome seemed likely. On the evening of the fourth day of coma the administration of Amigen 5 per cent in 5 per cent dextrose was begun by the slow intravenous drip method. When 100 cc. of the solution had been administered, a chill occurred. The intravenous drip medication was discontinued. The temperature rose rapidly to 105.8 F. and the pulse rate rose to 164 or higher. The application of cold wet packs and the use of ice water enemas were followed by a gradual decline of the temperature to 103 F., at which point these measures were discontinued. Shock ensued, with an irregular thready pulse and a steady fall of the blood pressure to 70 systolic and zero diastolic. At that point the pulse could not be felt. Epinephrine hydrochloride given intramuscularly resulted in a temporary response. Respirations were extremely shallow and gasping. Nikethamide administered intravenously concomitantly with 10 per cent dextrose brought about improvement in pulse rate and blood pressure. From that time improvement was steady. Partial return to consciousness followed in about forty-eight hours, and speech returned slowly with long intervals of a semicomatose state.

The authors are to be congratulated on a splendid therapeutic result; however, the emphasis laid on the fact that Amigen was the direct cause of the collapse and the assumption that Amigen may give rise to serious foreign protein reactions do not seem to me to be consonant with the evidence presented. The shock symptoms in this patient might reasonably be attributed to the toxic effects of the inordinately large dose of phenobarbital taken, and this deduction is supported by the description of the toxic symptoms of barbiturate poisoning given by Goodman and Gilman (The Pharmacological Basis of Therapeutics, New York, Macmillan Company, 1941, pp. 140-142). It would offer an explanation for (1) coma, (2) prolonged respiratory depression, (3) anoxia, (4) vasodilatation, (5) fall in blood pressure and (6) hypostatic pneumonia resulting from the shallow respiration and low blood pressure. It is known that a person who survives severe barbiturate poisoning for twenty-four to thirty-six hours manifests the shock symptoms on the fourth day or later. In this instance the shock symptoms were most pronounced on the fourth day, and return to normal did not occur for several succeeding days.

It would therefore seem to me more proper to attribute the shock symptoms to the barbiturate poisoning, which antedated the giving of Amigen, for the Amigen was administered at the height of the shock symptoms and when the patient was still in coma. Although the Amigen was promptly discontinued when the chill and sudden rise of temperature occurred in the course of its administration, the patient still remained in coma for several days.

Further, we cannot ignore the fact that the chill and hyperpyrexia may have resulted from a "pyrogen" in the tubing of the intravenous apparatus used for the Amigen. Such pyrogenic reactions are known to occur in intravenous therapy. It has been amply demonstrated that when the tubing is properly prepared such reactions do not occur in the administration of Amigen.

If the reaction is laid to Amigen on the basis of allergy, I fail to see how a rise in temperature can be reconciled with this thesis. Were this an anaphylactic shock reaction, a fall in blood pressure would most likely fit in with a "canine type" of anaphylaxis, in which *instance the temperature invariably falls.* Furthermore, there were no allergic manifestations of a respiratory or dermal character, and the response to epinephrine was indifferent, all of which would militate against allergy as a basis for the reaction.

Hence I do not feel that adequate evidence is presented to support the deduction of the authors that Amigen was responsible for a nearly fatal anaphylactic type of reaction. It appears more likely that a "pyrogen" due to faulty preparation of the tubing was responsible for the rise in temperature. The shock symptoms, I believe, were due to the barbiturate poisoning. The sudden rise in temperature perhaps served as a jolt to the waning cardiovascular and respiratory systems and was beneficent rather than harmful. The stimulating effects of nikethamide and the diuretic benefits of 10 per cent dextrose added further to the patient's recovery.

All shock symptoms noted clinically should not be attributed too readily to an allergic reaction. The use of such a term as "apparent sensitivity" to describe a shock reaction is misleading. "Cardiovascular collapse" or "alarm reaction" might better have been used to describe the shock reaction in this case. The rise in temperature must remain as an isolated symptom unrelated to the collapse the patient suffered.

BRET RATNER, M.D., New York.

DIET LOW IN SALT

To the Editor:—The discussion of Drs. Wheeler, Bridges and White's paper "Diet Low in Salt (Sodium) in Congestive Heart Failure" in THE JOURNAL January 4 was of special interest to me. Dr. Frederick Allen refers to his early work in 1920 concerning the salt free diet and claims priority for many clinical results and conclusions. I should like to refer to the work of the late Hermann Strauss, medical director of the Jewish Hospital in Berlin, Germany, whose early investigations about the role of salt in edema date back to the beginning of this century. In his book "The Nephritis" (1907), Strauss discussed at length the role of a saltless diet in edema and followed it up in his book "Practical Hints in the Saltless diet," published in 1910. Ever since that time Strauss had stressed in his publications the importance of a saltless diet in the treatment of edematous cardiac conditions.

I want to mention Strauss's name in this connection because his work seems to be forgotten in this country owing to the fact that since 1933 there had been no mutual contact in the medicine of this country and Germany. I happen to know these details, having worked with Strauss for seven years till 1941. A scientific appreciation of his work by me will be published this year in the Robinson Anniversary Volume (under the editorship of Dr. S. R. Kagan of Boston).

Hermann Strauss died in 1942 in a German concentration camp as a victim of Nazism.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Blood Grouping Tests Held Not to Be Conclusive Evidence of Paternity.—The plaintiff, by her guardian ad litem, commenced a bastardy proceeding against the defendant for the purpose of obtaining allowances for medical care, support and attorneys' fees. From adverse portions of the judgment, the defendant appealed to the district court of appeal, second district, division two, California.

Prior to the plaintiff's birth, her mother and the defendant entered into a stipulation providing, among other things, that within four months after the birth of the child the plaintiff, the mother and the defendant would all submit themselves to a blood grouping test by certain physicians chosen in accordance with the provisions of the stipulation. The purpose was to determine the paternity of the child, and the stipulation was signed by the plaintiff's guardian ad litem and by the defendant. After the plaintiff's birth the tests were made, the physicians, whose qualifications, competence and integrity are not questioned, reporting as follows:

> Examination of the bloods of Charles Chaplin, Joan Berry and Carol Ann Berry give the following results:
>
> | | Group | Type |
> |---|---|---|
> | Charles Chaplin | O | MN |
> | Joan Berry | A | N |
> | Carol Ann Berry | B | N |
>
> Conclusion reached as the result of these blood grouping tests is that, in accordance with the well accepted laws of heredity, the man, Charles Chaplin, cannot be the father of the child, Carol Ann Berry. The law of heredity which applies here is "The agglutinogens A and B cannot appear in the blood of a child unless present in the blood of one or both parents."

Two of the physicians testified at the trial that the report truly represented their findings from the tests made. They and one other physician testified that by reason of said tests defendant was not and could not have been the father of the plaintiff. The report and the evidence of the physicians were not controverted by any scientific evidence but were before the jury to be considered with all the evidence in the case. According to the evidence, the so-called A and B test was discovered about 1900 and the M and N test about 1930. It may be argued that because defendant's blood was type MN and the bloods of both Miss Berry and plaintiff were type N, defendant might have been the father of the plaintiff. One physician testified "We could not have excluded him on such an incomplete test," and another "We could not rule him out." But it appears from the evidence that the M and N test was an incomplete test and study of the bloods of the respective parties, and that the A and B test was necessary to an authentic and complete report.

Were the blood tests conclusive that defendant was not the father of the plaintiff? The court held that they were not and based its holding on *Arais* v. *Kalensnikoff*, 10 Calif. (2d) 428, 74 P. (2d) 1043, the only reported case in California in which blood tests were used for the purpose of attempting to determine the parentage of a child. In that case the court held that the evidence concerning the blood test "is expert opinion because the conclusions reached by the examiner are based upon medical research, and involve questions of chemistry and biology with which a layman is entirely unfamiliar," but that such tests and the evidence thereof are not conclusive because not so declared by the code and further that expert testimony is to be given the weight to which it appears to be justly entitled. Continuing, the district court said, conceding the immutability of the scientific law of blood grouping, which we have no reason to question, the infallibility of the results of blood tests depends upon the skill employed in making them. Errors are reported due to (1) the lack of training of the serologist; (2) the use of commercial serums; (3) the failure to make a countertest. When scientific testimony and evidence as to facts conflict, the jury or the trial court must determine the relative weight of the evidence. The law makes no distinction between expert evidence and that of any other character. The decision in the Arais case, concluded the court, has been the subject of discussion and criticism in law reviews and other legal periodicals but not by other courts as far as we have been able to ascertain, and it remains the law of this state until modified or overruled by the court that rendered the opinion. Accordingly, the judgment in favor of the plaintiff was affirmed.

In a specially concurring opinion, one of the Supreme Court judges announced that he concurred in the judgment because of the fact that the court was bound by the decision of the Supreme Court in *Arais* v. *Kalensnikoff* but added that he believed that the Supreme Court was in error in its determination of that case. In his specially concurring opinion he said that the ascertainment of the factual truth in the adjudication of any controversy is a consummation devoutly to be wished. Time was when the courts could rely only on human testimony. But modern science brought new aids. The microscope, electricity, x-ray, psychology, psychiatry, chemistry and many other scientific means and instrumentalities have revised the judical guessing game of the past into an institution approaching accuracy in portraying the truth as to the actual fact where, in the pursuit of which, scientific devices may be applied. The chemical tests for learning the presence of poisons in the blood stream, application of the roentgen ray in defining the fracture of a bone, the use of the microscope in acquiring exact knowledge of the authorship of documents, of the presence of bacteria or of the prevalence of white corpuscles—all argue eloquently for a reliance on scientific devices for ascertaining the truth. If the courts do not utilize these unimpeachable methods for acquiring accurate knowledge of pertinent facts, they will neglect the employment of available, potent agencies which serve to avoid miscarriages of justice. In conclusion the concurring justice said in the case at bar a widely accepted scientific method of determining parentage was applied. Its results were definite. To reject the new and certain for the old and uncertain does not tend to promote improvement in the administration of justice.—*Berry v. Chaplin, 169 P. (2d) 442 (Calif., 1946).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Feb. 8, page 423.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Various centers, March 17-19. *Part III.* Durham, Oct. 21-23. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Oral.* Los Angeles, April 11-12. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written.* Various centers, March 24. Final date for filing application is Feb. 17. *Oral.* New York City, April 25-27. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Chicago, March 17. *Oral.* Chicago, April 24-26. Final date for filing application is Feb. 15. Asst. Sec., Dr. W. A. Werrell, 1 W. Main St., Madison 3, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY. *Oral.* Examination to be given during the Summer. Applications for examination will be accepted until Feb. 15. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Part II.* Pittsburgh. June 1-7. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: *Oral. All Groups. Parts I and II.* Chicago, October. *Final date for filing application is March 1.* Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: *Oral.* St. Louis, April 16-20. Chicago, Oct. 7-11. Sec., Dr. D. M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PATHOLOGY: Philadelphia, June 3-4. Final date for filing application is April 15. Sec., Dr. Robert A. Moore, Euclid Ave. and Kings Highway, St. Louis 10.

AMERICAN BOARD OF PEDIATRICS: Effective May 1, application fee will be $125.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medicine, New York

1:583-714 (Dec.) 1946. **Partial Index**

Studies on Chronic Thyrotoxic Myopathy. G. W. Thorn and H. A. Eder.—p. 583.
*Disturbance in Salt and Water Metabolism in Hypertension. G. A. Perera and D. W. Blood.—p. 602.
Thiouracil in Angina Pectoris. W. S. Reveno.—p. 607.
Effects of Quinacrine (Atabrine) Suppression on Course of Pacific Vivax Malaria. I. M. London, P. H. Lavietes, K. E. Peterson and H. Most.—p. 615.
*"Muscle Spasm" in Acute Low Back Pain and Similar Syndromes: New Method of Treatment with Curare (d-Tubocurarine in Oil and Wax). E. B. Schlesinger and C. Ragan.—p. 621.
Subacute Bacterial (Streptococcus Viridans) Endocarditis Treated with Penicillin. R. L. McMillan.—p. 628.
Folic Acid and Bone Marrow in Radiation Therapy. P. L. Davis.—p. 634.
Clinical Vibrometer: Apparatus to Measure Vibratory Sense Quantitatively. W. S. Collens, J. D. Zilinsky and L. C. Boes.—p. 636.
Planning of Camp for Diabetic Children. H. J. John.—p. 642.

Disturbance in Salt and Water Metabolism in Hypertension.—Perera and Blood made observations on 12 control subjects and 12 patients with uncomplicated hypertensive vascular disease following the rigid withdrawal of sodium chloride for twenty-four hours. Despite an otherwise constant regimen, sodium restriction was followed by significant weight loss and increased urine output in control subjects which was not evident in hypertensive patients. The authors think that this difference in response indicates a disturbance in salt and water metabolism in hypertension referable to renal changes probably mediated by the adrenal cortex.

Curare in "Muscle Spasm" in Acute Low Back Pain.—According to Schlesinger and Ragan "muscle spasm" is often an integral part of the clinical picture of the acute low back syndrome. A suspension of d-tubocurarine in oil and wax has proved very useful in breaking up the muscle spasm. The difference in the response of patients exhibiting root compression from those with other types of disorders is described and is suggested as a diagnostic test. The use of d-tubocurarine in oil and wax for the prevention of deformity and alleviation of pain in early rheumatoid arthritis has led to promising results in a small group of patients.

*Reverse Approach to Fluorine-Dental Caries Hypothesis. R. A. Downs and F. S. McKay.—p. 1307.

Fat in Diet During Recovery from Infectious Hepatitis—Hoagland and his associates made a comparative study between the effects of a diet low in fat and high in protein and a diet relatively high in fat and high in protein on the period required for recovery in 70 patients with infectious hepatitis in whom there was moderate to severe acute liver insufficiency. No harmful effects were observed to follow the diet high in fat in patients in whom the intake of protein was kept correspondingly high. Indeed, the diet high in fat appeared to have decided advantages over the diet low in fat. With the former diet, weight loss was minimal in the acute stages of hepatitis and gain in weight maximal in convalescence. Added evidence of the superiority of the high fat, high protein diet was indicated by the results of serial tests of sulfobromophthalein retention, which revealed normal levels for the patients on the high fat, high protein diet earlier than the group on the high protein, low fat regimen.

Fluorine-Dental Caries Hypothesis.—Downs and McKay present a study that was brought about by reports from Montrose, Colo., that the dental caries rate was extremely high, and that the city water supply contained 1.4 parts per million of fluorine. A high dental caries rate and 1.4 parts per million of fluorine in the water supply do not usually exist together, and further investigation was deemed necessary. Examination of the high blood population revealed that some had a high rate of caries while others had fluorosis and a low rate of caries. A considerable number of the students with fluorosis had been born and reared in Spring Creek Mesa, where the water was obtained from deep wells. The pupils raised in these two districts—Spring Creek Mesa and the city of Montrose—only 5 to 10 miles apart, present a totally different picture in regard to dental caries. The only conclusion that could be reached was that the report which gave the fluorine content of the city water as 1.4 parts of fluorine per million was in error. This was established through a later analysis, which revealed that the correct fluorine content was 0.3 part per million.

Visit to Roentgen Laboratory in 1923. P. C. Hodges.—p. 642.

Intrabronchial Instillation of Iodized Oil.—Kooperstein and Bass report 3 cases of bilateral pneumonia which developed following intrabronchial instillation of iodized oil. The coincidence of the development of bilateral basal pneumonia in the portions of the lung fields previously instilled with iodized oil associated with hives and eosinophilia and occurring in known cases of bronchial asthma seemed to warrant further investigation. Sensitivity tests in the cases reported and in controls seemed to incriminate the iodized oil as the agent responsible for the acute pulmonary episodes. It is a matter of conjecture as to why more than a week passed before the onset of pneumonia, although there may be a relationship between the form in which iodine is present in poppyseed oil and its ability to act as a sensitizing agent. It is noteworthy that the time between instillation of iodized oil and onset of pneumonia resembled the "delayed reaction" of serum sickness.

Primary Amyloidosis of Lungs.—Dirkse says that, whereas the secondary type of amyloidosis, as it occurs in association with some chronic disease, is fairly familiar, the primary or atypical form, in which no antecedent condition appears to offer a background for the deposition of amyloid, is far less frequently encountered. After listing the characteristics of the primary form, on which a diagnosis of atypical or primary amyloidosis, as opposed to the secondary type, may be based, the author adds to the growing list of cases of primary amyloidosis a case involving primarily the lungs, mediastinum, lymph nodes and spleen. He describes the x-ray characteristics of the intrathoracic form of this condition and reviews x-ray findings previously recorded in these and other organs.

Roentgen Treatment of Bursitis of Shoulder.—Young says that the results obtained with roentgen therapy in 87 patients with bursitis of the shoulder indicate that it is a valuable form of treatment for cases manifesting acute and subacute forms of the disease. All but 2 of the patients with acute bursitis were relieved of pain, and the majority were well in one week or less. The responses in the subacute group were not as prompt, but more than two thirds reported complete relief of pain in two weeks or less and only a few were not benefited. Only one third of the group with chronic symptoms were cured, and almost 50 per cent reported no relief of pain.

Amebiasis in American Troops in India.—Klatskin reviews observations on 748 cases of amebiasis seen in American troops stationed in India. The clinical features were mild to moderate intermittent diarrhea, often accompanied with other gastrointestinal symptoms. Amebiasis was a common cause of urticaria and angioneurotic edema. Amebiasis of the liver was a common complication and varied in severity from an acute abscess to a low grade chronic hepatitis. Emetine alone cured 68 of the 69 cases. In some cases appendicitis appeared to be due directly to the ameba, while in others it appeared that the ameba had played a secondary role in opening avenues for bacterial infection. The most reliable diagnostic procedure was the demonstration of the trophozoites of Endameba histolytica in fresh stools passed after a large saline purge. The routine administration of moderate doses of emetine improved the end results of treatment with chiniofon, carbarsone and diodoquin. Serious toxic reactions were rare, even with large doses of emetine, when the patient was kept at bed rest and observed carefully.

Propylthiouracil in Hyperthyroidism.—Propylthiouracil having been proved the most active substance in several hundred compounds that have been studied in animals, it was used by Astwood and VanderLaan in 100 unselected cases of hyperthyroidism. Considerable individual variation in the minimal effective dose was observed, some patients requiring as little as 50 and some others as much as 150 mg. daily to restore metabolic equilibrium. It was concluded that 50 mg. every eight hours is approximately the optimal dose for the routine treatment of the more severe cases, that 50 mg. twice daily is adequate for milder ones, and that an effective dose should be continued until all manifestations of the disease have been controlled before smaller maintenance doses are substituted. The use of this medication was unattended with significant side effects.

*Intravenous Injection of Sodium Amytal as Test for Latent Anxiety. S. Susselman, F. Feldman and S. E. Barrera.—p. 567.

Neurologic Disease After Infections.—Bronson says that a neurologic syndrome apparently infectious in origin has been reported among the members of the armed forces of the United States in the recent war. Some investigators have assumed that the disorder was caused by infection with Corynebacterium diphtheriae. There is, however, considerable reason to doubt that C. diphtheriae is the sole etiologic agent. Thirteen patients with a postinfectious neurologic syndrome were studied in a general hospital in Australia in 1943. Attempts to isolate a filtrable virus were unsuccessful. There was no evidence to suggest that the condition was the result of diphtheritic infection. Sixty patients with a similar disturbance were studied at Moore General Hospital in 1945. Of these, the neurologic syndrome followed proved cutaneous diphtheria in 5, proved faucial diphtheria in 2 and severe sore throat which was probably diphtheritic in 5 others. There was no evidence to suggest that diphtheritic infection had played any part in the disease of the remaining 48 patients.

Sodium Amytal in Testing for Latent Anxiety.—Susselman and his associates state that sodium amytal in doses of 1½ grains (0.1 Gm.) given intravenously will frequently relieve a symptom which is entirely due to tension within one to five minutes. The same amount of sodium amytal will relieve that portion of the symptom due to tension in instances in which tensional pain is superimposed on pain of organic cause. Thus sodium amytal can be used as a diagnostic test to separate symptoms of organic disease from tension symptoms. The test should be used only to supplement thorough physical and psychiatric investigation.

Human Bartonella Infection and African Sleeping Sickness. D. Weinman.—p. 647.

Indications for Surgery in Gastric and Duodenal Ulcers.—Hinton says that the patient with gastric ulcer is more likely to be recommended for an operation than the patient with a duodenal ulcer because of the danger of malignant degeneration in gastric ulcer. In not more than 10 per cent of gastric ulcers should there be a question as to the diagnosis. In the questionable cases an immediate operation should be advised. Gastric ulcers respond more readily to medical management than do duodenal ulcers. The mortality from routine subtotal resections for gastric ulcer far exceeds the possibility of malignant degeneration in cases in which operation is not performed. Only those duodenal ulcers which fall in the chronic intractable group should be operated on. So-called pyloric obstruction is not an indication for operation. Massive hemorrhage in the majority of cases should be treated conservatively with blood transfusion.

Vocational Rehabilitation in Illinois.—It is the responsibility of the Illinois Division of Vocational Rehabilitation to help in the vocational rehabilitation of the estimated 56,000 persons who can be aided to become productive. Pearson and Darling think that members of the medical profession should be familiar with the division and its services in order to give information to the handicapped. The deaf and hard of hearing, epileptic, cardiac, tuberculous and blind patients, the orthopedically crippled, the mentally ill and others are eligible for service if there is a reasonable possibility that the individual will be able to engage in an occupation after rehabilitation. Services available include surgical care, medical care and psychotherapy, specialist's care in all fields, hospitalization up to ninety days for any one disability, physical therapy and occupational therapy, prosthetic devices and the like. After the patient is physically ready for employment he may be trained for a job. In Illinois it cost approximately $186 last year to rehabilitate an individual, but it cost as much as $500 each year to support a dependent handicapped person.

Immunity in Infectious Hepatitis.—Havens found that 9 human volunteers convalescent from experimentally induced infectious hepatitis were resistant when reinoculated with the same strain of virus six to nine months later. Eight out of 12 previously healthy control subjects developed infectious hepatitis with jaundice following administration of this same material.

Vaccination with Formolized Mumps Virus.—Stokes and his associates inoculated active mumps virus into 41 vaccinated and 32 unvaccinated children after obtaining the consent of parents or guardians. The result obtained indicated that mumps virus obtained from the parotid gland of the infected monkey and inactivated by formaldehyde and then used as a vaccine increased the resistance of about half of those to whom it was administered.

Treatment of Macrocytic Anemia with Lactobacillus Casei Factor.—Goldsmith administered L. casei factor (pteroylglutamic acid) to 15 patients between the ages of 4 and 69 with anemia. The dose varied from 5 to 120 mg. daily. Five of the patients have been studied for more than six months. Two patients with pernicious anemia, 4 with nutritional macrocytic anemia and 1 with normocytic anemia in which the bone marrow was depressed showed pronounced clinical and hematologic improvement when L. casei factor was given as the sole therapeutic agent. Two patients with sprue and 1 with a celiac syndrome improved in certain respects, but the blood picture was altered in only 1 instance. L. casei factor was ineffective in the treatment of 2 patients with aplastic anemia and of 1 patient each with macrocytic anemia associated with regional ileitis and myxedema and macrocytic anemia of unknown origin.

Pellagra in American Prisoners of War in the Philippines.—Lewis and Musselman say that symptoms of pellagra first appeared with dramatic suddenness in August 1942. Within symptoms of the disease. They complained of soreness and burning of their mouths and tongues. The tip of the tongue presented the typical raw, spotted appearance. Later ulcerations appeared on the tongue. The angles of the mouth became macerated and presented a perlèche-like membrane. A seborrheic lesion appeared about the alae of the nose and spread over the lips and chin. The skin lesions were more extensive than those usually described as pellagrous. Processed foods, a crude yeast culture and pure vitamin preparation were effective in controlling pellagra. Pure vitamin preparations were more effective when the diet was more adequate. The daily multivitamins utilized during 1944 reduced the incidence of the severe pellagra seen in 1942 and 1943.

Dihydroergotamine (D. H. E. 45) in Migraine.—Pollock presents brief histories of 17 patients with migraine in which he employed dihydroergotamine, known also as D. H. E. 45. Prophylactic treatment (0.5 cc. once or twice a week) was found beneficial in prolonging the interval and easing the severity of attacks. During a full blown attack of migraine, 1 to 1.5 cc. intravenously aborts an attack within fifteen to twenty minutes in many cases. The substance is not particularly effective in hypertensive cases.

Lipoma of Corpus Callosum.—Amyot reports a lipoma of the corpus callosum in a woman aged 39 who since her childhood had suffered from severe headache and for the last four years from convulsive attacks. Diagnosis was made with the aid of pneumoencephalography. A mental syndrome of frontal type and a right hemiplegia resulted from the surgical removal of the lipoma. This postoperative neuropsychic symptomatology may be ascribed to the lesion of the corpus callosum associated with a left frontal softening.

Angina Pectoris and Anemia.—Gélinas reports the occurrence of pernicious anemia associated with angina pectoris in a man who for the past few months had suffered from severe retrosternal pain on walking, from anorexia and from weakness. The blood count revealed 1,400,000 red and 4,000 white blood corpuscles. The hemoglobin was reduced to 42 per cent. The patient received six intramuscular injections of 2 cc. of liver extract containing 15 antianemic units per cubic centimeter in ten days. The retrosternal pains subsided within five days. In the absence of any other treatment, one injection of 2 cc. of the liver extract twice a month was sufficient for the control of the anemia. The patient did not experience any precordial pain for four years.

Weil's Disease.—Robertson reports 40 cases of Weil's disease occurring between the ages of 5 and 78 years. The condition was encountered four or five times every year during the period of the last ten years. Nearly 50 per cent of the cases have been diagnosed within the first four days of the illness and specific treatment started. The blood urea level has been raised from the earliest stages in all the cases. Its determination is the most important single pathologic investigation. A careful inquiry into the patient's work, home surrounding and habits with regard to bathing in fresh water is of the utmost importance. Twelve patients have been given specific antileptospiral serum during the first four days of the illness and one other received penicillin within the first two days. In this group there has been no mortality. This compares favorably with the remainder of the patients, none of whom received treatment until after the fourth day and among whom there were six fatalities—a mortality of 30 per cent. Penicillin when used freely during the early septicemic stage may be of greater usefulness than serum. Fifty per cent glucose intravenously (50 cc. every eight hours) proved valuable. The mechanism of cortical renal ischemia is of great importance in the etiology of the syndrome of water and nitrogen retention seen in the more severe cases of Weil's disease and may explain the apparent success of spinal analgesia in reestablishing renal function by invoking sympathetic release. The need for early use of this treatment in oliguric cases is emphasized.

Lung Lesions in Skeletal Tuberculosis.—Studies of the respiratory tract of 500 patients with skeletal tuberculosis revealed active pulmonary lesions in 284, or 57 per cent. This is in agreement with figures obtained by other observers. The primary complex was found in most of the children, and hematogenous foci in adults. The respiratory tract thus appears to be the route of entry of the tubercle bacillus even in skeletal tuberculosis. The infecting organism is therefore most likely to be the human type from human open pulmonary cases. Milk infected with bovine tubercle bacilli can no longer be considered an important source of skeletal tuberculosis. The skeletal lesion in most children originates soon after the primary infection. In most adults it is due to reactivation of quiescent tuberculous foci resulting in blood stream dissemination and subsequent implantation in bone and lung. Mann emphasizes the importance of routine radiography of the chest in the diagnosis and prognosis of skeletal tuberculosis.

Anuria Treated by Renal Decapsulation and Peritoneal Dialysis.—Reid and his associates report a case in which an incompatible blood transfusion was followed by uremia. It was unsuccessfully treated by all the commonly recognized methods and finally yielded to decapsulation of the kidneys, the associated uremia being relieved by the use of the peritoneum as a dialysing membrane. Twice normal saline solution was given intraperitoneally by drip injection, and later the fluid was drained off. By this method much urea was eliminated by dialysis through the peritoneum, with relief of uremic symptoms. Reid and his associates state that the patient, a woman, fully recovered.

*Another Case of Successful Prostatectomy in the Tenth Decade. W. de V. Scholtz.—p. 718.

Curare in Shock Treatments for Mental Patients.—Cohen used curare in the form of intocostrin in treating 14 patients undergoing shock treatment for psychoses. He found it most useful. Not only does it prevent fractures and painful spasm of muscles, but in cases in which painful spasm already exists curare can be used to allow treatment to proceed. It was quite common formerly to drop treatments owing to painfulness. Alcoholic addicts do not respond so well to this treatment. Cyanosis and respiratory difficulties are greater. Hence neostigmine should be used to neutralize the curare as soon as the convulsions are over. There is less recollection of the treatment and less fear if curare is used with shock therapy.

Successful Prostatectomy in the Tenth Decade.—Scholtz adds his report of a successful two-stage suprapubic prostatectomy performed on a man aged 91 to a report of 2 similar cases treated by Frater. The patient continued to be well more than two years later.

*White Blood Formula in Cirrhoses of Liver. P. de Graciansky and M. Mouzon.—p. 665.
Consequences of World War II in Czechoslovakia from Psychiatric Point of View. O. Janota.—p. 667.

White Blood Formula in Cirrhoses of Liver.—De Graciansky and Mouzon studied the white blood picture in 114 cases of cirrhosis of the liver. Seventeen cases of cirrhosis associated with pulmonary or cutaneous infection, with massive visceral hemorrhage and cases of Banti's disease were excluded as possible sources of error. Neutrophil polynucleosis was demonstrated in 92 of the remaining 97 cases, and it was associated with a myelocyte reaction in 19 cases. The importance of the neutrophil polynucleosis equals that of anemia and of thrombopenia in the hematologic syndrome of cirrhosis; in addition, the neutrophil polynucleosis represents an element of unfavorable prognosis. Essential eosinophilia may on the contrary be considered a favorable sign, while aneosinophilia suggests an unfavorable prognosis.

*Treatment of Cancer of Prostate with Estrogenic Substances. J. A. Weijtlandt.—p. 375.

Treatment of Cancer of Prostate with Estrogenic Substances.—Weijtlandt treated 12 patients with cancer of the prostate with estrogenic substances. In general intramuscular administration is preferred with 5 mg. of diethylstilbestrol or 10 mg. of dimenformon (estradiol) daily for two to three weeks. The same dose may then be administered three or two times or once a week. After one or two months of this treatment a weekly maintenance dose of 2.5 mg. of diethylstilbestrol or 5 mg. of estradiol is suggested. No untoward reactions were observed in spite of large total doses up to 1,000 mg. except for occasional gynecomastia, which subsided when the treatment was discontinued.

Influence of Sauna (Finnish) Bath on Cold Reactions of Cutaneous Vessels. W. Jung.—p. 1058.
Practice of Plasma Transfusions. S. von Salis.—p. 1062.

Diagnosis of Splenic Rupture.—Bieri observed lymphopenia in the presence of leukocytosis within a few hours after rupture of the spleen in 3 cases. For instance there was a decline in lymphocytes from 10 per cent to 3 per cent in one hundred and five minutes and from 16 per cent to 7 per cent in ninety minutes. Thus, if splenic rupture is suspected the diagnosis can be corroborated by investigation of the number of lymphocytes. The blood picture should be examined also in intra-abdominal hemorrhages that are not caused by splenic rupture.

Emetine in Pyogenic Infections.—Melchior found that hepatic abscesses observed in Ankara respond to emetine, although the majority of these abscesses are not caused by amebic dysentery. Emetine has proved effective also in nonamebic pulmonary abscesses and in various acute surgical infections that are accompanied with pus formation. The author presents 17 cases in which emetine proved successful after surgical treatment alone had failed to cure. The cases included among others postoperative peritonitis, furuncles, phlegmons, pleural empyemas, septicemia, renal abscess and dental infections.

*Comparative Study of Skin Reactions to Injections of Either Tuberculin or BCG Cultures. F. Civeira and R. Urioste.—p. 175.
Atypical Pain in Coronary Infarct. M. M. Frade Fernández.—p. 179.

Skin Reactions to Tuberculin and BCG Cultures.—Civeira and Urioste gave intracutaneous injections of solutions of either tuberculin or BCG in progressive concentrations to 18 patients with tuberculosis. The concentrations used for the first injections were 1: 1,000,000 for tuberculin and 1: 10,000,000 for the BCG cultures. A reaction of visible and palpable infiltration and erythema 10 mm. in diameter denoted the threshold of positivity. There is no relation between the threshold of positivity to the injection of tuberculin and to that of BCG cultures. The type of skin reaction is different for one or the other reactive agent. High concentration of BCG cultures may cause either local false reaction because of a personal sensitization to albumin or local formation of minute abscesses. The causes and mechanism of either tuberculin or BCG positive reaction are different.

Acute Otitis. Chlanda.—p. 635.
Roentgen Treatment of Acute and Chronic Unspecific Inflammations. H. Stech.—p. 637.

Panaris.—Domanig considers progressive panaris an emergency which requires immediate surgical intervention under conduction anesthesia with 2 cc. of a 2 per cent procaine hydrochloride solution or under mild narcosis. Deep proximal and distal incisions should be made at the area of the most pronounced swelling and of the severest pain; they should be extended to the healthy tissues under visual control, which may be insured by using Esmarch's bandage. Patients with involvement of tendon sheet should be admitted to a hospital. Immobilization with splint and plaster of paris cast is imperative, and change of dressing should not be performed earlier than on the fifth or sixth postoperative day.

*Treatment of Lupus Vulgaris with Vitamin D_2 and Calcium. E. H. Hermans.—p. 1312.

Vitamin D_2 and Calcium for Lupus Vulgaris.—The new treatment for lupus vulgaris recommended by Hermans was first described by Charpy in 1943. During the first week of treatment the patients are given 3 times 15 mg. of vitamin D_2 in alcoholic solution (1 mg. contains 40,000 units). After that they are given the 15 mg. twice a week. The calcium is provided by giving from 1 to 2 liters of milk daily and on twenty days each month 0.5 Gm. of calcium gluconate. This form of oral heliotherapy has produced favorable results, but it involves some danger of excessive dosage of vitamin D.

*Occurrence of Diphtheria in Recent Years, with a Special View to Influence of Antidiphtheric Vaccination. V. Mortensen.—p. 283.

Thresher's Lung.—Törnell describes 8 cases of thresher's lung. This condition is caused by the inhalation of dust from molded ("burned") grain. In the severe cases the onset is sudden, accompanied with shivering, fever, malaise and cough with mucopurulent or sanguinolent expectoration, and dyspnea. Eye symptoms and rhinitis may also occur. The clinical signs include a bronchial catarrh at the bases with dry subcrepitation, mild leukocytosis and an increased sedimentation rate. The x-ray picture resembles that of miliary tuberculosis. In severe cases the densities increase and merge into a disseminated patchy fibrosis with bronchiectasis. Cultivation of sputum samples on Sabouraud's medium yields Monilia, a yeastlike fungus; that is, thresher's lung is a bronchomoniliasis. Treatment with potassium iodide seemed to exert a noticeable influence on the mild cases of thresher's lung.

Erythroblastosis in Adults.—Nordenson reports 3 cases of erythroblastosis in adults. The disease is chronic, and the anemia is resistant to all treatments. There is considerable splenomegaly, and the red and white blood pictures are very immature because of an extramedullary hemopoiesis, which can be demonstrated by a splenic puncture. Even in cases in which the blood picture is atypical there exists a characteristic splenogram. The sternal marrow is hypoplastic. The liver function seems to be normal, and there are no signs of increased hemolysis. The etiology of the disease is unknown, and there is no effective treatment. Splenectomy is contraindicated.

Diphtheria in Recent Years.—Reviewing a material of 573 cases of diphtheria from the period between 1939 and 1945, Mortensen finds that diphtheria has been more frequent in 1944 and 1945 than during the preceding years. The age distribution has shifted in that in 1944-1945 only about one third of all the patients were children, as against about three fourths in the preceding years. Antidiphtheric vaccination has protected the children. The case mortality was 9.3 per cent for the nonvaccinated patients and 1.1 per cent for the vaccinated. The disease was milder in the vaccinated patients than in the nonvaccinated, and complications were far more frequent in the latter. Among the factors that contributed to the rise in diphtheria morbidity the author mentions greater possibilities of infection owing to poor hygienic conditions during the war and lowered resistance in the last years of the war.

Paroxysmal Tachycardia, Transitory Flutter and Fibrillation.—Jervell investigated 168 cases of paroxysmal tachycardia, including cases of transitory flutter and flutter with fibrillation. This group included 67 cases of degenerative heart disease, 16 with rheumatic, 4 with syphilitic and 11 with thyrotoxic disorders. Seventy patients had no signs of organic heart disease. Among 34 cases of flutter or fibrillation without organic heart disease there was only 1 case of permanent fibrillation. In the other cases the flutter or fibrillation subsided either spontaneously or after treatment. Paroxysmal tachycardia and transitory flutter and fibrillation are probably due to the same causes. The predisposing factor is assumed to consist of structural alterations in the muscle. Besides degenerative and rheumatic disorders of the myocardium, infections, adiposity and other disorders may be imagined to produce functional derangements. In some cases flutter or fibrillation follows physical exertion, and it is suggested that certain persons are predisposed to flutter and fibrillation. Increased tonus of the sympathetic probably plays a part in most cases. A number of case histories are reported which support the view that both a predisposing and a provocative factor play a part in paroxysmal tachycardia and transitory flutter and fibrillation.

Patent Ductus Botalli in Three Sisters.—Kjaergaard describes the histories of three sisters in a family of five children who had patent ductus Botalli. The parents were well, not related and gave no history of heart lesions. The oldest daughter, aged 11, and a boy aged 2 were free from the cardiac defect, but 3 girls aged 7 years, 6 years and 11 months, respectively, had patent ductus Botalli. The author thinks that the entire family ought to be examined whenever an instance of patent ductus Botalli is ascertained and also when any other form of congenital heart lesion is encountered.

Book Notices

The Child from Five to Ten. By Arnold Gesell, M.D., Director of the Clinic of Child Development, School of Medicine, Yale University, New Haven, Connecticut, and Frances L. Ilg, M.D., Assistant Professor of Child Development. In collaboration with Louise Bates Ames,-Ph.D., and Glenna E. Bullis. Cloth. Price, $4. Pp. 475, with illustrations. Harper & Brothers, 49 E. 33d St., New York 16; 90 Great Russell St., London W. C. 1, 1946.

This book, by the director and staff members of Yale Clinic of Child Development, is a campanion work to the earlier volume "Infant and Child in the Culture of Today" (1943). It is based on studies of 50 or more children at age levels 5, 5½, 6, 7, 8, 9 and 10 years. The observations at each level are systematically referred to ten major "fields of behavior," i. e. motor characteristics, personal hygiene, emotional expression, fears and dreams, self and sex, interpersonal relations, play and pastimes, school life, ethical sense and philosophic outlook. After a presentation in cross section of child life at the several age levels the ten areas of behavior are reviewed in panoramic fashion.

The study evidences the carefulness of observation that has made the work of the Yale Clinic such an important contribution to our knowledge of child development. Authentic, lively, realistic descriptions of how children behave, what they say and do and how they react to their environment are presented. The emerging patterns of behavior, modified by the maturing of the developing organism, are traced. The authors are sound in their emphasis on the total complex of a behaving organism in a changing environment.

Yet the student of child life and the clinician will sense the deep lack in this work, the lack that consistently characterizes the fine work of the Yale Clinic. Despite the authors' emphasis in the final chapter on "developmentalism" the work remains consistently on the descriptive level and lacks the dynamic quality that can be imparted to any account of the mental life of a human being only through a synthesizing, dynamic psychology. Such a psychology lurks at the fringes of the authors' comments and is almost desperately sought for in an attempt to attain the needed synthesis. Those aspects of childhood life that have to do with the more subjective mental life, i. e. emotional expression, fears and dreams, self and sex and ethical sense, carefully documented as they are, lose much of their meaning unless understood in terms of the dynamic interplay of psychologic forces actually observable in childhood life. This is not specifically acknowledged or recognized by the authors in relation to their own work. That they are by no means insensitive to this is evidenced by the fact that the best presentation of the subjective state of a child is not derived from their observations but quoted from the autobiographic work of Edmund Gosse. The profound implication to the child on discovering that the father is not infallible is made vividly clear by Gosse's account. Perhaps the "clinical observer" might with some justice maintain that we cannot "observe" a child's subjective state—perhaps we must rely on his ability to report it at a later date. However, a wealth of clinical observation bearing on the subjective life of the child is available in the works of child psychologists and psychoanalysts, together with precisely the sort of integrating dynamic concepts of the development of the childhood personality useful to an understanding of the facts reported so carefully in this work. Indeed, such recording of precise observation is what is required to correct, modify or confirm the current theories of child development.

Also revealing the lack of a basic dynamic psychology is the statement of the authors, in commenting on the possible fate of mankind, that "the intrinsic charm and goodness of childhood still constitute the best guaranty of the further perfectibility of mankind" (page 453). This is a charming sentiment but a highly unscientific statement. The development of ethical concepts furthering a higher order of society is dependent on a process involving the relationship of developing children with ethical parents; processes which involve early conditioning, introjection and identification eventually enable the child to assume the responsible attitudes of the mature adult. It is this process that could profitably be an object of study by the authors of this important book.

The Diagnosis and Treatment of Bronchial Asthma. By Leslie N. Gay, Ph.B., M.D., Assistant Professor of Medicine of the Johns Hopkins University School of Medicine, Baltimore. With a foreword by Warfield T. Longcope, A.B., M.D., Professor of Medicine of the Johns Hopkins University School of Medicine, Baltimore. Cloth. Price, $5. Pp. 334, with 80 illustrations. The Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1946.

The author has had about twenty-five years of experience in the field of allergy at Johns Hopkins University and in private practice. This book is an accounting of his experience and is most interesting both because he is a pioneer in this field and because of his special investigations in several aspects of the problems.

The book deals with the physiology of normal respiration and that observed in asthma and then takes up the etiology, pathology, diagnosis, differential diagnosis, complications and treatment of asthma. There is an excellent chapter on the pathology of asthma, with a detailed description of autopsy findings in 24 patients in whom asthma was the sole cause of, or was a factor in, death. The psychosomatic aspects of asthma are well portrayed, better than in any other book on the subject. Many case reports are given, and there are numerous illustrations and tables. The relationship of the nose and nasal sinuses to asthma is well stated, though many physicians are reluctant to advise nasal surgical intervention as frequently as does this author.

This book is not well balanced. The author failed to realize that in a relatively small book he has devoted far too much space to the particular subjects in which he has done special investigative work. Among these are pathology of asthma, the use of potassium salts, oral ragweed treatment, allergic rhinitis, ephedrine and the use of radium for adenoid tissue. His essays on the discovery of helium and on the virtues of Bermuda as a hay fever resort are entirely out of place. In all these subjects a shorter discussion would have been better, and the interested reader should have been referred to other sources for more information. Because of this excessive waste of space there is much too little discussion on the more ordinary but more important phases of treatment. The chapter on etiology is meager; important causes of asthma, e. g., horse dander, are hardly mentioned. More space should have been given for treatment so that the average medical student or physician could better treat his asthmatic patients.

The role of foods in asthma is belittled, though most observers feel that foods are important. There are no diet lists and nowhere can the source of allergens be found. The index is inadequate; it contains no reference to such important allergens as cottonseed and dog, cat or horse dander. Although house dust is an important cause of asthma, there are no special instructions to patients on how to reduce exposure.

Mixtures of extracts, e. g. pollen from ragweed, grass and tree, are given. Many workers object to this procedure because one cannot safely raise dosages during the respective pollen seasons, yet the aim of all is to reach the highest dosage just before the pollen season. The addition of a potent allergen, as cottonseed, to such a mixture is extremely dangerous and ill advised.

The author states (page 120) that "the inaccuracy of this procedure (skin tests by the scratch method) has been recognized by experience and the majority of authorities on this subject prefer the more readily controlled intracutaneous method." This statement is challenged. The scratch tests are widely used and are informative, and they are perfectly safe. Fatalities have occurred and continue to occur even in the hands of specialists who inject their extracts without preliminary scratch tests. Both methods should be used. The bibliography is rather small, though probably sufficient for a book of this size.

Encyclopedia of Psychology. Edited by Philip Lawrence Harriman and Written by Many Contributors. Fabrikoid. Price, $10. Pp. 897, with illustrations. The Philosophical Library, Inc., 15 E. 40th St., New York 16, 1946.

The 900 pages of this book bear testimony to the tremendous accretion of knowledge in this social science. More than 80 eminent psychiatrists, psychologists, psychoanalysts and educators contributed to it, and the mass of the material is well nigh sufficient in its scope to deter the average physician from even beginning to read it. If, however, he can accumulate the time and the courage he will find here much that will be exceedingly useful to him in the problems of his practice. He will wish, however, to read selectively in the special fields related to his medical practice. A mere glance at the headings, such as "Climate and Human Behavior," "Feeblemindedness," "Hypnoanalysis" and "Lobotomy," give an indication of the scope of the book. Each of the sections, which are arranged alphabetically, is supplemented with an extensive bibliography.

Principles of Hematology with 106 Illustrative Cases. By Russell L. Haden, M.A., M.D., Chief of the Medical Division of the Cleveland Clinic, Cleveland, Ohio. Third edition. Cloth. Price, $5. Pp. 366, with 171 illustrations. Lea & Febiger, South Washington Square, Philadelphia 6, 1946.

The third edition of this excellent book adds the technic of bone marrow puncture and the analysis of the marrow films. The section on technic is extremely comprehensive, and the illustrations are unusually good. The subject matter is treated from the point of view of the mechanism of normal and disturbed hematopoiesis, rather than the systematic consideration of disease entities. One hundred and six short clinical abstracts are given, illustrating types of blood abnormalities encountered in practice. A consideration of the Rh factor (and erythroblastosis) was intentionally omitted by the author to simplify the discussion of fundamental principles. The book is an ideal introduction to the subject and should serve to present hematology as a dynamic, rather than a purely morphologic, study.

Astrophysique. Le sang: Structure des hématies; la molécule d'hémoglobin, molécules de folliculine, de lutéine et de testostérone; coagulation du sang; maladies de la nutrition. Par le Docteur G. Froin. Paper. Price, 240 francs. Pp. 228, with illustrations. Girardot et C^ie^, 27, Quai des Grands-Augustins, Paris, 6^e^, 1946.

The most remarkable feature of this book is that the date is 1946 instead of 1346. It sets the clock back at least six centuries, possibly more. In a series of most curious diagrams, there is a startling combination of chemical formulas with the names of the different planets and references to the north and south poles. The application of astrophysics to the chemical constitution of the blood, sex hormones and nutritional maladies is not new, having been treated by the Chaldean metaphysicians, but the present treatise brings it up to date. The book makes a valuable contribution to modern medical curiosities.

A Memoir to the Academy of Sciences at Paris on a New Use of Sulphuric Ether. By W. T. G. Morton. Presented by M. Arago in the Autumn of 1847. With a foreword by John F. Fulton. Publication No. 14, Historical Library, Yale Medical Library. Paper. Price, $1.50. Pp. 24. Henry Schuman, 20 East 70th St., New York 21, 1946.

The Centennial of Surgical Anesthesia: An Annotated Catalogue of Books and Pamphlets Bearing on the Early History of Surgical Anesthesia Exhibited at the Yale Medical Library, October 1946. Compiled by John F. Fulton, M.D., and Madeline E. Stanton, A.B. Paper. Price, $4. Pp. 102, with 9 illustrations. Henry Schuman, 20 East 70th St., New York 21, 1946.

With an introduction by Dr. John F. Fulton, the publisher makes available a letter sent by W. T. G. Morton to the Academy of Sciences at Paris. The letter gives the background of the discovery and states clearly the evidence on which are based his claims in relation to those of Wells and Jackson.

Simultaneously, the same publisher makes available an annotated catalogue of books and pamphlets bearing on the early history of surgical anesthesia. Any physician interested in the background of what is perhaps the second greatest discovery ever made in medical science will wish to have a copy of this excellent historical contribution.

Dentistry: An Agency of Health Service. By Malcolm Wallace Carr, D.D.S., Director of Oral Surgery and Visiting Oral Surgeon, Metropolitan Hospital, New York. Studies of The New York Academy of Medicine, Committee on Medicine and the Changing Order. Cloth. Price, $1.50. Pp. 219. The Commonwealth Fund, Division of Publications, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1946.

In addition to Dr. Carr nineteen distinguished contributors nationally known in fields of dental education, research, clinical practice and public health, prepared this volume.

The book itself is developed in six parts—History, Education, Dental Practice, Research, Dental Socio-Economics and part six, the summary and conclusions.

Through the book the philosophy that dentistry in all its parts is and should be autonomous and not under the control of the medical profession is warmly supported.

Dentistry as an organized profession is one hundred and six years old. During this period dentistry has developed from a highly technical craft to a full-fledged profession engaged in an effort to maintain health in the mouth and the body as a whole. This book traces some of the steps taken during the century to bring dentistry to its present position as "a part of the great pattern of public health care."

In part three, Dental Practice, the problems of Dentistry in Industry, Public Health Dentistry, Dental Practice in Rural Areas and Dentistry for Negroes are discussed.

The chapter on Dentistry for Negroes deals frankly with the problem of both dental service for the Negro and also the many difficulties of the Negro dentist. Every fair-minded professional man could agree with the statement made at the close of the chapter that "the new perspective of dentistry should include the integration of all qualified and ethical dental practitioners into organized dentistry, regardless of race or religion."

The importance of research in advancing the knowledge of dental caries and the periodontal affections which "have long been known as diseases characterized by high attack rates with no effective available method of mass control" is very properly stressed. It is through research in these areas that dentistry may be able to make its greatest contribution to the public "as an agency of health service."
